

# FILTERS IN TOPOLOGY

## 1. INTRODUCTION

In these short notes we study filters of subsets with their applications to topological spaces. Filters were introduced in [Cartan, 1937] as an effective tool in studying general topological spaces. Here we recapitulate Cartan's results. In particular, we give a concise proof of Tychonoff's theorem on compact spaces.

## 2. FILTERS

**Definition 2.1.** Let  $X$  be a set and let  $\mathcal{F}$  be a nonempty family of subsets of  $X$ . Assume that the following assertions hold.

- (1)  $\mathcal{F}$  is closed under finite intersections.
- (2) If  $F_1$  and  $F_2$  are subsets of  $X$  such that  $F_1 \in \mathcal{F}$  and  $F_1 \subseteq F_2$ , then  $F_2 \in \mathcal{F}$ .

Then  $\mathcal{F}$  is a *filter of subsets of  $X$* .

We note the following fact.

**Fact 2.2.** Let  $X$  be a set and let  $\{\mathcal{F}_i\}_{i \in I}$  be a family of filters of subsets of  $X$ . Then

$$\bigcap_{i \in I} \mathcal{F}_i$$

is a filter of subsets of  $X$ .

*Proof.* Left for the reader as an exercise. □

**Definition 2.3.** Let  $X$  be a set and let  $\mathcal{F}$  be a filter of subsets of  $X$ . If  $\emptyset \notin \mathcal{F}$ , then  $\mathcal{F}$  is a *proper filter*.

Filters are functorial as it is displayed in the following notion.

**Definition 2.4.** Let  $\mathcal{F}$  be a filter of subsets of a set  $X$  and let  $f : X \rightarrow Y$  be a map. Then a filter

$$f(\mathcal{F}) = \{Z \subseteq Y \mid \text{there exists } F \in \mathcal{F} \text{ such that } f(F) \subseteq Z\}$$

of subsets of  $Y$  is the *image of  $\mathcal{F}$  under  $f$* .

Let us note the following results.

**Fact 2.5.** Let  $\mathcal{F}$  be a filter of subsets of a set  $X$  and let  $f : X \rightarrow Y$  be a map. If  $\mathcal{F}$  is a proper filter, then  $f(\mathcal{F})$  is a proper filter.

*Proof.* Left for the reader as an exercise. □

Now we introduce the notion of ultrafilter and prove its properties. Finally by invoking axiom of choice we prove that ultrafilters exist.

**Definition 2.6.** Let  $\mathcal{F}$  be a proper filter of subsets of a set  $X$  such that for every proper filter  $\tilde{\mathcal{F}}$  of subsets of  $X$  if  $\mathcal{F} \subseteq \tilde{\mathcal{F}}$ , then  $\mathcal{F} = \tilde{\mathcal{F}}$ . Then  $\mathcal{F}$  is an *ultrafilter of subsets of  $X$* .

**Proposition 2.7.** Let  $X$  be a set and let  $\mathcal{F}$  be a proper filter of subsets of  $X$ . The following assertions are equivalent.

- (i)  $\mathcal{F}$  is an ultrafilter of subsets of  $X$ .
- (ii) For each subset  $F$  of  $X$  either  $F \in \mathcal{F}$  or  $X \setminus F \in \mathcal{F}$ .

*Proof.* Assume that  $\mathcal{F}$  is an ultrafilter and let  $F$  be a subset of  $X$ . Suppose that  $F \notin \mathcal{F}$ . Then the smallest filter containing  $\{F\} \cup \mathcal{F}$ , which exists according to Fact 2.2, is not a proper filter. This implies that there exists  $F' \in \mathcal{F}$  such that  $F \cap F' = \emptyset$ . Since  $F' \subseteq X \setminus F$  and  $\mathcal{F}$  is a filter, we derive that  $X \setminus F \in \mathcal{F}$ . This proves that (i)  $\Rightarrow$  (ii).

Suppose that (ii) holds. Consider a filter  $\tilde{\mathcal{F}}$  such that  $\mathcal{F} \subsetneq \tilde{\mathcal{F}}$ . If  $F \in \tilde{\mathcal{F}} \setminus \mathcal{F}$ , then  $X \setminus F \in \mathcal{F}$  and hence  $\emptyset = F \cap (X \setminus F) \in \tilde{\mathcal{F}}$ . This implies that  $\tilde{\mathcal{F}}$  is not a proper filter. Thus  $\mathcal{F}$  is an ultrafilter of subsets of  $X$ . This completes the proof of (ii)  $\Rightarrow$  (i).  $\square$

**Corollary 2.8.** Let  $f : X \rightarrow Y$  be a map of sets and let  $\mathcal{F}$  be an ultrafilter of subsets of  $X$ . Then  $f(\mathcal{F})$  is an ultrafilter.

*Proof.* Filter  $f(\mathcal{F})$  is proper according to Fact 2.5. Fix a subset  $Z$  of  $Y$ . By Proposition 2.7 either  $f^{-1}(Z) \in \mathcal{F}$  or  $f^{-1}(Y \setminus Z) \in \mathcal{F}$ . Thus either  $Z \in f(\mathcal{F})$  or  $Y \setminus Z \in f(\mathcal{F})$ . Proposition 2.7 implies that  $f(\mathcal{F})$  is an ultrafilter.  $\square$

**Proposition 2.9.** Let  $X$  be a set and let  $\mathcal{F}$  be a proper filter of subsets of  $X$ . Then there exists an ultrafilter  $\tilde{\mathcal{F}}$  of subsets of  $X$  such that  $\mathcal{F} \subseteq \tilde{\mathcal{F}}$ .

*Proof.* Consider the family

$$F = \{\mathcal{G} \mid \mathcal{G} \text{ is a proper filter of subsets of } X \text{ and } \mathcal{F} \subseteq \mathcal{G}\}$$

Note that  $F$  is nonempty because  $\mathcal{F} \in F$ . The inclusion introduces partial order on  $F$  and if  $L \subseteq F$  is a linearly ordered subset, then

$$\bigcup L$$

is a proper filter. Hence each chain in  $(F, \subseteq)$  admits an upper bound. Zorn's lemma implies that  $(F, \subseteq)$  has a maximal element  $\tilde{\mathcal{F}}$ . Clearly  $\tilde{\mathcal{F}}$  is an ultrafilter of subsets of  $X$  which contains  $\mathcal{F}$ .  $\square$

### 3. FILTERS AND CONVERGENCE IN TOPOLOGICAL SPACES

**Definition 3.1.** Let  $(X, \tau)$  be a topological space and let  $\mathcal{F}$  be a proper filter of subsets of  $X$ . Consider a point  $x$  in  $X$ . Suppose that for every open neighborhood  $U$  of  $x$  with respect to  $\tau$  we have  $U \in \mathcal{F}$ . Then  $\mathcal{F}$  converges to  $x$  with respect to  $\tau$ .

**Proposition 3.2.** Let  $(X, \tau), (Y, \theta)$  be topological spaces and let  $f : X \rightarrow Y$  be a map. Then the following assertions are equivalent.

- (i)  $f$  is a continuous map  $(X, \tau) \rightarrow (Y, \theta)$ .
- (ii) If  $\mathcal{F}$  is a proper filter of subsets of  $X$  convergent to some point  $x$  with respect to  $\tau$ , then  $f(\mathcal{F})$  converges to  $f(x)$  with respect to  $\theta$ .
- (iii) If  $\mathcal{F}$  is an ultrafilter of subsets of  $X$  convergent to some point  $x$  with respect to  $\tau$ , then  $f(\mathcal{F})$  converges to  $f(x)$  with respect to  $\theta$ .

*Proof.* Suppose that  $f$  is a continuous map  $(X, \tau) \rightarrow (Y, \theta)$ . Fix a proper filter  $\mathcal{F}$  of subsets of  $X$  convergent to  $x$  with respect to  $\tau$ . Fix an open neighborhood  $V$  of  $f(x)$  with respect to  $\theta$ . By continuity of  $f$  we have  $f^{-1}(V) \in \tau$ . Thus  $f^{-1}(V)$  is an open neighborhood of  $x$  with respect to  $\tau$ . Hence  $f^{-1}(V) \in \mathcal{F}$  and we infer that  $V \in f(\mathcal{F})$ . Since  $V$  is arbitrary open neighborhood of  $f(x)$  with respect to  $\theta$ , we derive that  $f(\mathcal{F})$  converges to  $f(x)$  with respect to  $\theta$ . This proves the implication (i)  $\Rightarrow$  (ii).

The implication (ii)  $\Rightarrow$  (iii) follows by definition of ultrafilter.

Suppose now that (iii) holds. Fix a point  $x$  in  $X$  and consider an open neighborhood  $V$  of  $f(x)$  with respect to  $\theta$ . Define

$$\mathcal{F} = \{F \subseteq X \mid U \setminus f^{-1}(V) \subseteq F \text{ for some open neighborhood } U \text{ of } x \text{ with respect to } \tau\}$$

Then  $\mathcal{F}$  is a filter of subsets of  $X$ . If  $\mathcal{F}$  is a proper filter, then Proposition 2.9 asserts that there exists an ultrafilter  $\tilde{\mathcal{F}}$  containing  $\mathcal{F}$ . Since  $\mathcal{F}$  converges to  $x$  with respect to  $\tau$ , we derive that  $\tilde{\mathcal{F}}$  converges to  $x$  with respect to  $\tau$ . Thus  $f(\tilde{\mathcal{F}})$  converges to  $f(x)$  with respect to  $\theta$ . Note that

$$f(X \setminus f^{-1}(V)) \in f(\tilde{\mathcal{F}})$$

This implies that  $Y \setminus V \in f(\tilde{\mathcal{F}})$  and hence  $V \notin f(\tilde{\mathcal{F}})$ . It follows that the filter  $f(\tilde{\mathcal{F}})$  cannot converge to  $f(x)$  with respect to  $\theta$ . Therefore,  $\mathcal{F}$  is not a proper filter. This means that there exists an open neighborhood  $U$  of  $x$  with respect to  $\tau$  such that  $U \subseteq f^{-1}(V)$ . This proves that  $f$  is continuous at  $x$  as a map  $(X, \tau) \rightarrow (Y, \theta)$ . Since  $x \in X$  is arbitrary, we derive (iii)  $\Rightarrow$  (i).  $\square$

**Theorem 3.3.** *Let  $(X, \tau)$  be a topological space. Then the following assertions are equivalent.*

- (i) *Each ultrafilter of subsets of  $X$  is convergent to some point of  $X$  with respect to  $\tau$ .*
- (ii)  *$(X, \tau)$  is a quasi-compact topological space.*

*Proof.* Suppose that (i) holds. Pick a family  $\{F_i\}_{i \in I}$  of closed and nonempty subsets of  $(X, \tau)$  which is closed under finite intersections. Then the family

$$\{F \subseteq X \mid F_i \subseteq F \text{ for some } i \in I\}$$

is a proper filter of subsets of  $X$ . By Proposition 2.9 there exists an ultrafilter  $\mathcal{F}$  of subsets of  $X$  which contains the filter defined above. According to (i) ultrafilter  $\mathcal{F}$  is convergent to some point  $x$  in  $X$  with respect to  $\tau$ . Then for every open neighborhood  $U$  of  $x$  with respect to  $\tau$  we have  $U \in \mathcal{F}$ . In particular,  $U \cap F_i \neq \emptyset$  for every  $i \in I$  and for every open neighborhood  $U$  of  $x$  with respect to  $\tau$ . Since  $F_i$  is closed for each  $i \in I$ , this implies that  $x \in F_i$  for every  $i \in I$ . Thus

$$x \in \bigcap_{i \in I} F_i$$

and this implies that  $(X, \tau)$  is quasi-compact. This completes the proof of (i)  $\Rightarrow$  (ii).

Assume that  $(X, \tau)$  is quasi-compact and suppose that  $\mathcal{F}$  is an ultrafilter of subsets of  $X$ . Suppose that  $\mathcal{F}$  is not convergent. Then for every  $x \in X$  there exists open neighborhood  $U_x$  of  $x$  with respect to  $\tau$  such that  $U_x \notin \mathcal{F}$ . Since  $(X, \tau)$  is quasi-compact, we deduce that there exist finite subset  $\{x_1, \dots, x_n\} \in X$  such that

$$X = \bigcup_{i=1}^n U_{x_i}$$

According to Proposition 2.7 we derive that  $X \setminus U_x \in \mathcal{F}$  for every  $x \in X$ . Hence

$$\bigcap_{i=1}^n (X \setminus U_{x_i}) \in \mathcal{F}$$

On the other hand we have

$$\bigcap_{i=1}^n (X \setminus U_{x_i}) = X \setminus \bigcup_{i=1}^n U_{x_i} = \emptyset$$

This is contradiction. Thus the implication (ii)  $\Rightarrow$  (i) holds.  $\square$

## 4. TYCHONOFF'S THEOREM

The following result is a celebrated theorem due to Tychonoff.

**Theorem 4.1.** *Let  $\{(X_i, \tau_i)\}_{i \in I}$  be a family of quasi-compact topological spaces. Then the product*

$$\prod_{i \in I} (X_i, \tau_i)$$

*is quasi-compact.*

*Proof.* We denote  $\prod_{i \in I} X_i$  by  $X$  and let  $\tau$  be the product of topologies  $\{\tau_i\}_{i \in I}$ . For each  $i$  in  $I$  we denote by  $pr_i : X \rightarrow X_i$  the canonical projection onto  $i$ -th factor. Suppose that  $(X_i, \tau_i)$  is a quasi-compact for every  $i \in I$ . Pick an ultrafilter  $\mathcal{F}$  of subsets of  $X$ . Fix  $i$  in  $I$ . According to Corollary 2.8 the filter  $pr_i(\mathcal{F})$  is an ultrafilter. Since  $(X_i, \tau_i)$  is quasi-compact, we derive that  $pr_i(\mathcal{F})$  is convergent to some point  $x_i \in X_i$  with respect to  $\tau_i$ . Let  $x$  be a point of  $X$  such that  $pr_i(x) = x_i$  for each  $i \in I$ . Fix finite subset  $\{i_1, \dots, i_n\} \subseteq I$ . Consider open neighborhood  $U_j$  of  $x_{i_j}$  with respect to  $\tau_{i_j}$  for  $j = 1, \dots, n$ . Then  $U_{i_j} \in pr_{i_j}(\mathcal{F})$  for each  $j$  and hence  $pr_{i_j}^{-1}(U_{i_j}) \in \mathcal{F}$  for each  $j$ . Since  $\mathcal{F}$  is a filter, we derive that

$$\prod_{j=1}^n U_{i_j} \times \prod_{i \in I \setminus \{i_1, \dots, i_n\}} X_i = \bigcap_{j=1}^n pr_{i_j}^{-1}(U_{i_j}) \in \mathcal{F}$$

This implies that  $\mathcal{F}$  is convergent to  $x$  with respect to  $\tau$ . Thus every ultrafilter in  $(X, \tau)$  is convergent and hence Theorem 3.3 shows that  $(X, \tau)$  is a quasi-compact topological space.  $\square$

**Theorem 4.2.** *Let  $\{(X_i, \tau_i)\}_{i \in I}$  be a family of nonempty topological spaces. If the product*

$$\prod_{i \in I} (X_i, \tau_i)$$

*is quasi-compact, then  $(X_i, \tau_i)$  is quasi-compact for every  $i \in I$ .*

*Proof.* We denote  $\prod_{i \in I} X_i$  by  $X$  and let  $\tau$  be the product of topologies  $\{\tau_i\}_{i \in I}$ . For each  $i$  in  $I$  we denote by  $pr_i : X \rightarrow X_i$  the canonical projection onto  $i$ -th factor. Assume that  $(X, \tau)$  is quasi-compact. Since  $X_i \neq \emptyset$  for every  $i \in I$ , we derive that  $pr_i : (X, \tau) \rightarrow (X_i, \tau_i)$  is a continuous and surjective map for every  $i \in I$ . Hence for each  $i \in I$  space  $(X_i, \tau_i)$  is quasi-compact as an image of a quasi-compact space under continuous map.  $\square$
