#### **BIAŁYNICKI-BIRULA FUNCTORS**

# 1. Introduction

In this notes we study Białynicki-Birula functors. In the first section we prove some results concerning the forgetful functor  $Rep(M) \to Rep(G)$ , where M is an affine monoid k-scheme and G is its group of units (we assume that G is open and schematically dense in M). These results will be used in the following sections.

We assume that *k* is a field. In these notes we use the following notational convention.

**Remark 1.1.** Since the Yoneda embedding  $\mathbf{Sch}_k \hookrightarrow \widehat{\mathbf{Sch}_k}$  is full and faithful, we identify  $\mathbf{Sch}_k$  with the subcategory of  $\widehat{\mathbf{Sch}_k}$  consisting of representable presheaves on  $\mathbf{Sch}_k$ . In particular, if X is a k-scheme, then we denote by the same symbol the presheaf representable by X.

### 2. TANNAKIAN FORMALISM FOR QUOTIENT STACKS

In this section we discuss an application of the main result of [Hall and Rydh, 2019]. For this we need to briefly discuss *algebraic stacks*, although for our purposes there is no need to use any technical details of this language. We refer the interested reader to the excellent exposition [Olsson, 2016] of this subject. We note the following facts.

- (1) An algebraic stack is a category fibered over  $\mathbf{Sch}_k$  satisfying certain extra conditions described in [Olsson, 2016, Definition 4.6.1] and [Olsson, 2016, Definition 8.1.4]. By [Olsson, 2016, Definition 8.2.1, Example 8.2.3] there are well defined notions of *locally noetherian*, *noetherian and excellent algebraic stacks*.
- (2) A morphism of algebraic stacks is a morphism of fibered categories over  $\mathbf{Sch}_k$ . If  $\mathcal{X}$  and  $\mathcal{Y}$  are algebraic stack, then we denote by  $\mathrm{Mor}(\mathcal{X},\mathcal{Y})$  the corresponding category of morphisms.
- (3) For every locally noetherian algebraic stack  $\mathcal{X}$  there exists an abelian monoidal category  $\mathfrak{Coh}(\mathcal{X})$  of coherent sheaves on  $\mathcal{X}$  ([Olsson, 2016, Definition 9.1.14]). If  $\mathcal{X}$  and  $\mathcal{Y}$  are locally noetherian algebraic stacks, then we denote by  $\operatorname{Hom}_{r,\otimes,\cong}(\mathfrak{Coh}(\mathcal{X}),\mathfrak{Coh}(\mathcal{Y}))$  the category of right exact, monoidal functors  $\mathfrak{Coh}(\mathcal{X}) \to \mathfrak{Coh}(\mathcal{Y})$  with natural isomorphism as morphisms.
- **(4)** If  $f: \mathcal{X} \to \mathcal{Y}$  is a morphism of locally noetherian algebraic stacks, then f induces the functor  $f^*: \mathfrak{Coh}(\mathcal{Y}) \to \mathfrak{Coh}(\mathcal{X})$  such that  $f^* \in \operatorname{Hom}_{r, \otimes, \cong}(\mathfrak{Coh}(\mathcal{X}), \mathfrak{Coh}(\mathcal{Y}))$ .
- (5) Let **G** be a locally algebraic group k-scheme and let X be a k-scheme equipped with an action of **G**. We consider  $\mathbf{Sch}_k$  as a Grothendieck site with respect to fppf topology ([Olsson, 2016, Example 2.1.14]). Next the quotient fibered category  $[X/\mathbf{G}]$  ([Monygham, 2020b, Definition 9.5]) with respect to this topology is an algebraic stack by [Olsson, 2016, Example 8.1.12].
- (6) In (5) if k-scheme X is locally noetherian (noetherian, excellent), then [X/G] is a locally noetherian (noetherian, excellent) by [Olsson, 2016, Definition 8.2.1, Example 8.2.3] and [Olsson, 2016, Example 8.1.12].
- (7) In (5) if k-scheme X is locally noetherian, then there exists an equivalence of monoidal categories  $\mathfrak{Coh}([X/\mathbf{G}]) \cong \mathfrak{Coh}_{\mathbf{G}}(X)$  ([Olsson, 2016, Exercise 9.H]). Moreover, this equivalence is functorial with respect to  $\mathbf{G}$ -equivariant morphism. That is if Y is another locally noetherian k-scheme with action of  $\mathbf{G}$  and  $f: X \to Y$  is a  $\mathbf{G}$ -equivariant morphism, then f induces a morphism  $[f/\mathbf{G}]: [X/\mathbf{G}] \to [Y\mathbf{G}]$  by [Monygham, 2020b, Theorem 9.7] and the square

1

$$\begin{array}{ccc} \mathfrak{Coh}([Y/\mathbf{G}]) & \xrightarrow{[f/\mathbf{G}]^*} \mathfrak{Coh}([X/\mathbf{G}]) \\ & & & \downarrow \cong \\ & & & \downarrow \cong \\ & \mathfrak{Coh}_{\mathbf{G}}(Y) & \xrightarrow{f^*} \mathfrak{Coh}_{\mathbf{G}}(X) \end{array}$$

of categories and functors is commutative.

**(8)** If **G** is smooth and affine over k, then  $[X/\mathbf{G}]$  has affine stabilizers.

**Remark 2.1.** Let Spec k be a point equipped with the trivial action of a smooth and affine group **G**. Then (7) together with [Monygham, 2020a, Example 4.7] impy that  $\mathfrak{Coh}([\operatorname{Spec} k/\mathbf{G}])$  can be identified with the category  $\operatorname{\mathbf{Repf}}_{\mathbf{G}}$  of finite dimensional representations of **G**.

Let us state the main result of [Hall and Rydh, 2019].

**Theorem 2.2** ([Hall and Rydh, 2019, Theorem 1.1]). Let  $\mathcal{X}$  be a noetherian algebraic stack with affine stabilizers. For every locally excellent algebraic stack  $\mathcal{T}$  the functor

$$\operatorname{Mor}(\mathcal{X},\mathcal{T}) \xrightarrow{f \mapsto f^*} \operatorname{Hom}_{r,\otimes,\cong} (\mathfrak{Coh}(\mathcal{T}),\mathfrak{Coh}(\mathcal{X}))$$

is an equivalence of categories.

Keeping our previous remarks in mind we deduce the following result.

**Corollary 2.3.** Let G be an smooth affine group k-scheme and let X, Z be k-schemes equipped with an action of G. Suppose that Z is noetherian and X is locally of finite type over k. Then

$$\operatorname{Mor}([Z/\mathbf{G}],[X/\mathbf{G}]) \xrightarrow{f \mapsto f^*} \operatorname{Hom}_{r,\otimes,\cong} \left( \mathfrak{Coh}([X/\mathbf{G}]), \mathfrak{Coh}([Z/\mathbf{G}]) \right)$$

is an equivalence of categories.

*Proof.* Note that [Z/G] is a noetherian algebraic stack according to **(5)** and **(6)**. It has affine stabilizers according to **(8)**. Similarly by **(5)** [X/G] is an algebraic stack. Moreover, it is locally excellent according to the fact that X is locally excellent (it is locally of finite type over k and k is a field) and **(6)**. Then by Theorem **2.2** we derive that the functor in the statement is an equivalence of categories.

**Corollary 2.4.** Let G be an smooth affine group k-scheme and let X, Z be k-schemes equipped with an action of G. Suppose that Z is noetherian and X is locally of finite type over k. Then we have a bijection

$$\left\{f:Z\to X\,\middle|\, f\text{ is }\mathbf{G}\text{-}equivariant}\right\}\xrightarrow{f\mapsto f^*} \left\{F\in \mathrm{Hom}_{r,\otimes,\cong}\left(\mathfrak{Coh}_{\mathbf{G}}(X),\mathfrak{Coh}_{\mathbf{G}}(Z)\right)\,\middle|\, F\cdot p_X^*=p_Z^*\right\}$$

where  $p_X^* : \mathbf{Repf}(\mathbf{G}) \to \mathfrak{Coh}_{\mathbf{G}}(X)$  and  $p_Z^* : \mathbf{Repf}(\mathbf{G}) \to \mathfrak{Coh}_{\mathbf{G}}(Z)$  are functors induced by  $\mathbf{G}$ -equivariant morphisms  $p_X : X \to \operatorname{Spec} k$  and  $p_Z : Z \to \operatorname{Spec} k$ , respectively.

*Proof.* Since fppf topology is subcanonical, [Monygham, 2020b, Theorem 9.7] shows that there exists a bijection

$$\{f: Z \to X \mid f \text{ is } \mathbf{G}\text{-equivariant}\} \xrightarrow{f \mapsto [f/\mathbf{G}]} \{h: [Z/\mathbf{G}] \to [X/\mathbf{G}] \mid [p_X/\mathbf{G}] \cdot h = [p_Y/\mathbf{G}]\}$$

Corollary 2.3 implies that there exists a bijection

$$\left\{h: [Z/\mathbf{G}] \to [X/\mathbf{G}] \,\middle|\, [p_X/\mathbf{G}] \cdot h = [p_Y/\mathbf{G}]\right\} \xrightarrow{h \mapsto h^*} \left\{F \in \mathrm{Hom}_{r, \otimes, \cong}\left(\mathfrak{Coh}([X/\mathbf{G}]), \mathfrak{Coh}([Z/\mathbf{G}])\right) \,\middle|\, F \cdot [p_X/\mathbf{G}]^* = [p_Z, \mathbf{G}]^*\right\}$$

Next (7) implies that there exists a bijection

$$\left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}([X/\mathbf{G}]), \mathfrak{Coh}([Z/\mathbf{G}])\right) \, \middle| \, F \cdot [p_X/\mathbf{G}]^* = [p_Z, \mathbf{G}]^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}}(Z)\right) \, \middle| \, F \cdot p_X^* = p_Z^* \right\} \\ \longrightarrow \left\{F \in \operatorname{Hom}_{r, \otimes, \cong} \left(\mathfrak{Coh}_{\mathbf{G}}(X), \mathfrak{Coh}_{\mathbf{G}$$

and for a **G**-equivariant morphism  $f: Z \to X$  the image of  $[f/\mathbf{G}]^* : \mathfrak{Coh}([X/\mathbf{G}]) \to \mathfrak{Coh}([Z/\mathbf{G}])$  under this bijection is  $f^* : \mathfrak{Coh}_{\mathbf{G}}(X) \to \mathfrak{Coh}_{\mathbf{G}}(Z)$ . These imply that the map of classes

$$\left\{f:Z\to X\,\middle|\, f\text{ is }\mathbf{G}\text{-equivariant}\right\}\xrightarrow{f\mapsto f^*}\left\{F\in\mathrm{Hom}_{r,\otimes,\cong}\left(\mathfrak{Coh}_{\mathbf{G}}(X),\mathfrak{Coh}_{\mathbf{G}}(Z)\right)\,\middle|\, F\cdot p_X^*=p_Z^*\right\}$$

is a bijection.

Note that Corollary 2.4 relies on some asumptions regarding G, X and Z. It is worth noting that Joachim Jelisiejew and the author were able to obtain a slightly more general (yet unpublished) result.

**Theorem 2.5** ([Jelisiejew and Sienkiewicz, 2020, Theorem A.2]). Let G be an affine algebraic group over K. Let Z, X be K-schemes equipped with an action of G and assume that X is quasi-compact and quasi-separated. Suppose that  $F: \mathfrak{Q}coh_G(X) \to \mathfrak{Q}coh_G(Z)$  is a cocontinuous, monoidal functor such that  $F \cdot p_X^* = p_Z^*$ . Then there exists a unique G-equivariant morphism  $f: Z \to X$  such that  $f^* = F$ .

# 3. Relations between representations of a monoid and its group of units

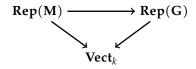

In this section we study the relation between the category  $\mathbf{Rep}(\mathbf{M})$  of representations of an affine monoid k-scheme  $\mathbf{M}$  and the category  $\mathbf{Rep}(\mathbf{G})$  of representations of its group of units  $\mathbf{G}$ . Let  $i:k[\mathbf{M}] \to k[\mathbf{G}]$  be the morphism of k-bialgebras induced by  $\mathbf{G} \hookrightarrow \mathbf{M}$ . Let us first note the following elementary result.

**Fact 3.1.** Assume that G is open and schematically dense in M. Then i is an injective morphism of k-algebras.

*Proof.* This follows from [Görtz and Wedhorn, 2010, Proposition 9.19]. □

**Fact 3.2.** The forgetful functor  $Rep(M) \rightarrow Rep(G)$  creates colimits and finite limits.

*Proof.* This follows from [Monygham, 2020d, Theorem 14.3, Theorem 14.4] and the commutative triangle

of functors.  $\Box$ 

The theorem below characterizes representations of G which are contained in the image of the forgetful functor  $Rep(M) \rightarrow Rep(G)$ .

**Theorem 3.3.** Assume that G is open and schematically dense in M. Let V be a G-representation. Then the following are equivalent.

- (i) V is in the image of the forgetful functor  $Rep(M) \rightarrow Rep(G)$ .
- (ii) The coaction  $d: V \to k[\mathbf{G}] \otimes_k V$  factors through  $i \otimes_k 1_V : k[\mathbf{M}] \otimes_k V \hookrightarrow k[\mathbf{G}] \otimes_k V$ .

*Proof.* In the proof we denote by  $\Delta_{\mathbf{M}}$  and  $\Delta_{\mathbf{G}}$  comultiplications of  $k[\mathbf{M}]$  and  $k[\mathbf{G}]$ , respectively. We also denote by  $\xi_{\mathbf{M}}$  and  $\xi_{\mathbf{G}}$  counits of  $k[\mathbf{M}]$  and  $k[\mathbf{G}]$ , respectively. According to Fact 3.1 i is an injective morphism of k-algebras.

Clearly (i)  $\Rightarrow$  (ii). We prove the converse. Suppose that (ii) holds. Let  $c: V \to k[\mathbf{M}] \otimes_k V$  be a unique morphism such that  $d = (i \otimes_k 1_V) \cdot c$ . It suffices to prove that c is the coaction of the bialgebra  $k[\mathbf{M}]$  on V. Observe that

$$(i \otimes_k i \otimes_k 1_V) \cdot (1_{k[\mathbf{M}]} \otimes_k c) \cdot c = (i \otimes_k d) \cdot c = (1_{k[\mathbf{G}]} \otimes_k d) \cdot d = (\Delta_{\mathbf{G}} \otimes_k 1_V) \cdot d =$$

$$= (\Delta_{\mathbf{G}} \otimes_k 1_V) \cdot ((i \otimes_k 1_V) \cdot c) = ((\Delta_{\mathbf{G}} \cdot i) \otimes_k 1_V) \cdot c = (i \otimes_k i \otimes_k 1_V) \cdot (\Delta_{\mathbf{M}} \otimes_k 1_V) \cdot c$$

Since  $i \otimes_k i \otimes_k 1_V$  is a monomorphism, we deduce that  $(1_{k[\mathbf{M}]} \otimes_k c) \cdot c = (\Delta_{\mathbf{M}} \otimes_k 1_V) \cdot c$ . Moreover, we have

$$(\xi_{\mathbf{G}} \otimes_k 1_V) \cdot d = (\xi_{\mathbf{G}} \otimes_k 1_V) \cdot ((i \otimes_k 1_V) \cdot c) = (\xi_{\mathbf{M}} \otimes_k 1_V) \cdot c$$

and hence  $(\xi_{\mathbf{M}} \otimes_k 1_V) \cdot c$  is the canonical isomorphism  $V \cong k \otimes_k V$ . Thus c is the coaction of  $k[\mathbf{M}]$  and  $d = (i \otimes_k 1_V) \cdot c$ . Therefore, V is in the image of  $\mathbf{Rep}(\mathbf{M}) \to \mathbf{Rep}(\mathbf{G})$ .

**Theorem 3.4.** Assume that G is open and schematically dense in M. Then Rep(M) is a full subcategory of Rep(G) closed under subobjects and quotients.

*Proof.* In the proof we denote by  $\Delta_{\mathbf{M}}$  and  $\Delta_{\mathbf{G}}$  comultiplications of  $k[\mathbf{M}]$  and  $k[\mathbf{G}]$ , respectively. We also denote by  $\xi_{\mathbf{M}}$  and  $\xi_{\mathbf{G}}$  counits of  $k[\mathbf{M}]$  and  $k[\mathbf{G}]$ , respectively. According to Fact 3.1 i is an injective morphism of k-algebras.

We first prove that  $\mathbf{Rep}(\mathbf{M})$  is a full subcategory of  $\mathbf{Rep}(\mathbf{G})$ . For this consider  $\mathbf{M}$ -representations V,W and a their morphism  $f:V\to W$  as  $\mathbf{G}$ -representations. Let  $c_V$  and  $c_W$  be coactions of  $k[\mathbf{M}]$  on V and W, respectively. Our goal is to prove that f is a morphism of  $\mathbf{M}$ -representations. Consider the diagram

$$k[\mathbf{G}] \otimes_{k} V \xrightarrow{1_{k[\mathbf{G}]} \otimes_{k} f} k[\mathbf{G}] \otimes_{k} W$$

$$i \otimes_{k} 1_{V} \qquad \qquad \uparrow i \otimes_{k} 1_{W}$$

$$k[\mathbf{M}] \otimes_{k} V \xrightarrow{1_{k[\mathbf{M}]} \otimes_{k} f} k[\mathbf{M}] \otimes_{k} W$$

$$\downarrow c_{V} \qquad \qquad \downarrow c_{W}$$

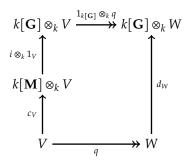

$$V \xrightarrow{f} W$$

in which the outer square is commutative. Our goal is to prove that the bottom square is commutative. We have

$$(i \otimes_k 1_W) \cdot c_W \cdot f = \left(1_{k[\mathbf{G}]} \otimes_k f\right) \cdot (i \otimes_k 1_V) \cdot c_V = (i \otimes_k 1_W) \cdot \left(1_{k[\mathbf{M}]} \otimes_k f\right) \cdot c_V$$

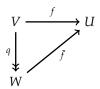

Since  $i \otimes_k 1_W$  is a monomorphism, we deduce that  $c_W \cdot f = (1_{k[\mathbf{M}]} \otimes_k f) \cdot c_V$ . Hence f is a morphism of  $\mathbf{M}$ -representations.

Next we prove that  $\mathbf{Rep}(\mathbf{M})$  is a subcategory of  $\mathbf{Rep}(\mathbf{G})$  that is closed under subquotients. Consider an  $\mathbf{M}$ -representation V and its quotient  $\mathbf{G}$ -representations  $q:V \twoheadrightarrow W$ . We show that W is a quotient  $\mathbf{M}$ -representation of V. Let  $c_V$  be the coaction of  $\mathbf{M}$  on V and let  $d_W$  be the coaction of  $\mathbf{G}$  on W. We have a commutative diagram

and hence  $d_W(W) \subseteq k[\mathbf{M}] \otimes_k W$ . Thus Theorem 3.3 implies that W is a representation of  $\mathbf{M}$  and q is a morphism of  $\mathbf{M}$ -representations. This shows that  $\mathbf{Rep}(\mathbf{M})$  is a subcategory of  $\mathbf{Rep}(\mathbf{G})$  closed under quotients. Next let  $j: U \hookrightarrow V$  be a  $\mathbf{G}$ -subrepresentation of a  $\mathbf{M}$ -representation V. By what we proved above the cokernel  $q: V \twoheadrightarrow W$  of j in  $\mathbf{Rep}(\mathbf{G})$  is contained in  $\mathbf{Rep}(\mathbf{M})$ . Since both  $\mathbf{Rep}(\mathbf{M})$  and  $\mathbf{Rep}(\mathbf{G})$  are abelian and the forgetful functor  $\mathbf{Rep}(\mathbf{M}) \rightarrow \mathbf{Rep}(\mathbf{G})$  is exact, we derive that the kernel of q in  $\mathbf{Rep}(\mathbf{M})$  coincides with its kernel in  $\mathbf{Rep}(\mathbf{G})$ . Thus U is a  $\mathbf{M}$ -representation and  $j: U \hookrightarrow V$  is a morphism of  $\mathbf{M}$ -representations. Hence  $\mathbf{Rep}(\mathbf{M})$  is the category of  $\mathbf{Rep}(\mathbf{G})$  closed under subobjects.

**Theorem 3.5.** Assume that **G** is open and schematically dense in **M**. Let V be a **G**-representation of **G**. There exists an **M**-representation W and a surjective morpism q:V woheadrightarrow W of **G**-representations such that for every **M**-representation U and a morphism f:V woheadrightarrow U of **G**-representations there exists a unique morphism  $\tilde{f}:W woheadrightarrow U$  of **M**-representations making the triangle

commutative.

*Proof.* Assume first that V is finite dimensional. Let  $\mathcal{K}$  be a set of **G**-subrepresentations of V that consists of all  $K \subseteq V$  such that V/K carries a structure of **M**-representation. Clearly  $\mathcal{K} = \emptyset$  because  $\{0\} \in \mathcal{K}$ . Since V is finite dimensional, there exists a finite subset  $\{K_1, ..., K_n\} \subseteq \mathcal{K}$  such that

$$\bigcap_{i=1}^{n} K_i = \bigcap_{K \in \mathcal{K}} K$$

Then a morphism

$$V/\left(\bigcap_{K\in\mathcal{K}}K\right)\ni v\mapsto \left(v\bmod K_i\right)_{1\leq i\leq n}\in\bigoplus_{i=1}^nV/K_i$$

is a monomorphism and hence by Theorem 3.4 the quotient  $W = V/(\bigcap_{K \in \mathcal{K}} K)$  is an **M**-representation. Let  $g: V \twoheadrightarrow W$  be the canonical epimorphism. Consider now a morphism  $f: V \to U$  of **G**-representations, where U is an **M**-representation. Then  $\operatorname{im}(f)$  is a **G**-subrepresentation of U and by Theorem 3.4 we derive that  $\operatorname{im}(f)$  is an **M**-representation. This implies that  $\ker(f)$  is in  $\mathcal{K}$ . Hence f factors through g. Thus there exists a unique morphism  $\tilde{f}: W \to U$  of **G**-representations such that  $\tilde{f} \cdot g = f$ . This completes the proof in case when V is finite dimensional.

Now consider the general V. Let  $\mathcal{F}$  be the set of all finite dimensional  $\mathbf{G}$ -representations of V. According to [Monygham, 2020d, Corollary 15.2] we deduce that  $V = \operatorname{colim}_{F \in \mathcal{F}} F$ . By the case considered above we deduce that for every F in  $\mathcal{F}$  there exists a universal morphism  $q_F : F \to W_F$  of  $\mathbf{G}$ -representations into an  $\mathbf{M}$ -representation  $W_F$ . Note that if  $F_1 \subseteq F_2$  are two elements of  $\mathcal{F}$ , then

$$\begin{array}{ccc}
F_1 & \xrightarrow{q_{F_1}} & W_{F_1} \\
\downarrow & & \downarrow \\
F_2 & \xrightarrow{q_{F_2}} & W_{F_2}
\end{array}$$

Thus  $\{W_F\}_{F\in\mathcal{F}}$  together with morphisms  $W_{F_1} \to W_{F_2}$  for  $F_1 \subseteq F_2$  in  $\mathcal{F}$  form a diagram parametrized by the poset  $\mathcal{F}$ . The category  $\mathbf{Rep}(\mathbf{M})$  has small colimits ([Monygham, 2020d, Corollary 14.5]) and we define  $W = \mathrm{colim}_{F\in\mathcal{F}}W_F$ . This is also a colimit of this diagram in the category  $\mathbf{Rep}(\mathbf{G})$  by Fact 3.2. We also define  $q = \mathrm{colim}_{F\in\mathcal{F}}q_F : V = \mathrm{colim}_{F\in\mathcal{F}}F \to W$ . Since a colimit of a family of epimorphisms is an epimorphism, we derive that q is an epimorphism of  $\mathbf{G}$ -representations. Suppose now that  $f: V \to U$  is a morphism of  $\mathbf{G}$ -representations and U is an  $\mathbf{M}$ -representation. Then  $f_{|F}$  uniquely factors through  $q_F$  for every F in  $\mathcal{F}$ . Hence by universal property of colimits we derive that f factors through g in a unique way. This completes the proof.

# 4. BIAŁYNICKI-BIRULA FUNCTORS

In this section we fix an affine group *k*-scheme **G**. Let **M** be an affine monoid *k*-scheme with zero **o** such that **G** is its group of units.

**Definition 4.1.** Let X be a k-scheme equipped with an action of G. For every k-scheme Y we define

$$\mathcal{D}_X(Y) = \{ \gamma : \mathbf{M} \times_k Y \to X \mid \gamma \text{ is } \mathbf{G}\text{-equivariant} \}$$

This gives gives rise to a subfunctor  $\mathcal{D}_X$  of  $\operatorname{Mor}_k(\mathbf{M} \times_k (-), X) : \operatorname{\mathbf{Sch}}_k^{\operatorname{op}} \to \operatorname{\mathbf{Set}}$ . We call it *the Białynicki-Birula functor of* X.

**Fact 4.2.** Let X be a scheme equipped with an action of G. Then  $\mathcal{D}_X$  is a Zariski sheaf.

*Proof.* This is a consequence of the fact that  $\operatorname{Mor}_k(\mathbf{M} \times_k (-), X)$  is a Zariski sheaf and if we glue **G**-equivariant morphisms, then the result is **G**-equivariant. Indeed, this shows that  $\mathcal{D}_X$  is a Zariski subsheaf of  $\operatorname{Mor}_k(\mathbf{M} \times_k (-), X)$ .

**Remark 4.3.** Let *X* be a *k*-scheme equipped with an action of **G**. Then there are canonical morphism of functors

$$\mathcal{D}_X \xrightarrow{i_X} X$$

$$s_X \left( \bigvee_{X^G} r_X \right)$$

which we define now. First let us explain that in the diagram X stands for the presheaf representable by the k-scheme X (Remark 1.1) and  $X^G$  denotes the functor of fixed points of X ([Monygham, 2020c, Definition 7.1]). Now fix k-scheme Y and  $\gamma \in \mathcal{D}_X(Y)$ , then we define

$$i_X(\gamma) = \gamma_{|\{e\}\times_{k}X} = \gamma \cdot \langle e, 1_X \rangle, r_X(\gamma) = \gamma_{|\{e\}\times_{k}X} = \gamma \cdot \langle e, 1_X \rangle$$

where  $e : \operatorname{Spec} k \to \mathbf{M}$  is the unit of  $\mathbf{M}$  and  $\mathbf{o} : \operatorname{Spec} k \to \mathbf{M}$  is the zero. Next if  $f : Y \to X$  is a morphism in  $X^{\mathbf{G}}(Y)$ , then we define

$$s_X(f) = f \cdot pr_Y$$

where  $pr_Y : \mathbf{M} \times_k Y \to Y$  is the projection. Finally note that  $r_X \cdot s_X = 1_{XG}$ .

**Remark 4.4.** Let X be a k-scheme equipped with an action of G. Then M (actually the presheaf of monoids represented by M) acts on  $\mathcal{D}_X$ . Indeed, fix k-scheme Y,  $\gamma \in \mathcal{D}_X(Y)$  and  $m: Y \to M$ . Then we define the product

$$m\gamma = \gamma \cdot \langle m, 1_{\gamma} \rangle$$

and this determines an action of **M** on  $\mathcal{D}_X$ . Moreover, with respect to this action  $i_X$  is **G**-equivariant and  $r_X$ ,  $s_X$  are **M**-equivariant ( $X^G$  is equipped with trivial action of **M**).

**Remark 4.5.** Let X,Y be k-schemes equipped with actions of G and let  $f:X\to Y$  be a G-equivariant morphism, then there exists a morphism of functors  $\mathcal{D}_f:\mathcal{D}_X\to\mathcal{D}_Y$  given by

$$\mathcal{D}_f(\gamma) = f \cdot \gamma$$

for every element  $\gamma$  of the functor  $\mathcal{D}_X$ .

Let *X* be a *k*-scheme equipped with an action of **G**. It is useful to discuss subfunctors of  $\mathcal{D}_X$  defined by closed **G**-stable subschemes of *X*.

**Theorem 4.6.** Let X be a k-scheme equipped with an action of the group G. Suppose that G is open and schematically dense in M. If  $j: Z \hookrightarrow X$  is a closed G-stable subscheme of X, then the square

$$\begin{array}{ccc}
\mathcal{D}_Z & \xrightarrow{\mathcal{D}_j} & \mathcal{D}_X \\
\downarrow^{i_Z} & & \downarrow^{i_X} \\
Z & \xrightarrow{j} & X
\end{array}$$

is cartesian in the category of presheaves on  $\mathbf{Sch}_k$ .

*Proof.* The fact that the square is commutative follows by examination of definitions in Remarks 4.3 and 4.5. Pick k-scheme Y,  $f: Y \to Z$  and  $\gamma \in \mathcal{D}_X(Y)$  such that  $j \cdot f = i_X(\gamma)$ . This is depicted in the diagram

$$f \longmapsto_{j} j \cdot f = \gamma_{|\{e\} \times_{k} X}$$

Our goal is to show that there exists a unique **G**-equivariant morphism  $\eta : \mathbf{M} \times_k Y \to U$  such that  $\mathcal{D}_j(\eta) = \gamma$  and  $i_Z(\eta) = f$ . This is depicted by the diagram

$$\frac{\eta}{r_{u}} \xrightarrow{\mathcal{D}_{j}} \gamma = j \cdot \eta$$

$$f = \eta_{|\{e\} \times_{k} X}$$

It suffices to prove that  $\gamma$  factors through j. First note that the assumption  $\gamma_{|\{e\}\times_k Y} = j \cdot f$  implies that

$$\gamma_{|\mathbf{G} \times_k Y} = j \cdot f \cdot pr_Y$$

where  $pr_Y: \mathbf{G} \times_k Y \to Y$  is the projection. This implies that  $\gamma_{|\mathbf{G} \times_k}$  factors through j. Consider scheme-theoretic preimage  $\gamma^{-1}(Z)$ . Then  $\gamma^{-1}(Z)$  is a closed  $\mathbf{G}$ -stable (as an inverse image of a  $\mathbf{G}$ -stable closed subscheme under the  $\mathbf{G}$ -equivariant morphism) subscheme of  $\mathbf{M} \times_k Y$ , which contains  $\mathbf{G} \times_k Y$ . Since  $\mathbf{G}$  is open, schematically dense in  $\mathbf{M}$  and k is a field, we derive that  $\mathbf{G} \times_k Y$  is open and schematically dense in  $\mathbf{M} \times_k Y$ . Thus  $\gamma^{-1}(Z) = \mathbf{M} \times_k Y$  and hence  $\gamma$  factors through j.

In order to prove interesting result in the spirit of Theorem 4.6 which concerns open **G**-stable subschemes, we need to assume that **M** is a Kempf monoid.

**Theorem 4.7.** Let X be a k-scheme equipped with an action of the group G of units of a Kempf monoid M. If  $j:U \hookrightarrow X$  is an open G-stable subscheme of X, then the square

$$\begin{array}{ccc}
\mathcal{D}_{U} & \xrightarrow{\mathcal{D}_{j}} & \mathcal{D}_{X} \\
\downarrow^{r_{U}} & & \downarrow^{r_{X}} \\
U^{G} & \xrightarrow{j^{G}} & X^{G}
\end{array}$$

is cartesian in the category of presheaves on  $Sch_k$ .

As we shall see this result follows from the following.

**Lemma 4.7.1.** Let K be an algebraicaly closed field over k. Suppose that

$$\mathbf{M}_K = \operatorname{Spec} K \times_k \mathbf{M}, \mathbf{G}_K = \operatorname{Spec} K \times_k \mathbf{G}$$

and let  $\mathbf{o}_K$  be the unique K-point of  $\mathbf{M}_K$  lying over  $\mathbf{o}$ . Let V be an open  $\mathbf{G}_K$ -stable subscheme of  $\mathbf{M}_K$  such that  $\mathbf{o}_K \in V$ . Then  $V = \mathbf{M}_K$ .

*Proof of the lemma.* Since  $\mathbf{M}$  is a Kempf monoid, there exists a closed embedding of monoids  $v: \mathbb{A}^1_K \hookrightarrow \mathbf{M}_K$  preserving zeros such that  $v_{|\mathbb{G}_{m,K}} \subseteq \mathbf{G}_K$ . Fix a point  $p \in \mathbf{M}_K$  and let  $u: \operatorname{Spec} k(p) \to \mathbf{M}_K$  be the associated morphism of K-schemes. Consider the composition

$$\mathbb{A}^1_{k(p)} = \mathbb{A}^1_K \times_K \operatorname{Spec} k(p) \xrightarrow{v \times_K u} \mathbf{M}_K \times_K \mathbf{M}_K \longleftrightarrow \mathbf{M}_K$$

where the second morphism is the multiplication. Clearly h is  $\mathbf{G}_{m,k(p)}$ -equivariant. Hence  $h^{-1}(V)$  is an open  $\mathbf{G}_{m,k(p)}$ -stable subscheme of  $\mathbb{A}^1_{k(p)}$  containing zero of this monoid k(p)-scheme (because  $\mathbf{o}_K \in V$  by assumption). Since the only open  $\mathbf{G}_{m,k(p)}$ -stable subscheme of  $\mathbb{A}^1_{k(p)}$  containing zero is  $\mathbb{A}^1_{k(p)}$ , we derive that  $h^{-1}(V) = \mathbb{A}^1_{k(p)}$ . Thus  $p \in V$ . Since p is arbitrary point of  $\mathbf{M}_K$ , we derive that  $V = \mathbf{M}_K$ .

*Proof of the theorem.* The fact that the square is commutative follows by examination of definitions in Remarks 4.3 and 4.5. Pick k-scheme Y,  $f \in U^G$  and  $\gamma \in \mathcal{D}_X(Y)$  such that  $j^G(f) = r_X(\gamma)$ . This is depicted in the diagram

$$f \longmapsto_{j^{\mathbf{G}}} j \cdot f = \gamma_{|\{\mathbf{o}\} \times_{k} X}$$

Our goal is to show that there exists a unique **G**-equivariant morphism  $\eta : \mathbf{M} \times_k Y \to U$  such that  $\mathcal{D}_i(\eta) = \gamma$  and  $r_U(\eta) = f$ . This is depicted by the diagram

$$\frac{\eta}{r_{u}} \xrightarrow{\mathcal{D}_{j}} \gamma = j \cdot \eta$$

$$f = \eta_{|\{\mathbf{o}\} \times_{k} X}$$

Fir this it suffices to prove that  $\gamma$  factors through j. Consider  $W = \gamma^{-1}(U)$ . Note that W is an open **G**-stable (as an inverse image of a **G**-stable open subscheme under the **G**-equivariant morphism) subscheme of  $\mathbf{M} \times_k Y$ , which contains  $\{\mathbf{o}\} \times_k Y$ . Lemma 4.7.1 asserts that for every geometric point  $\overline{y}$  of Y we have  $W_{\overline{y}} = \mathbf{M}_{k(\overline{y})}$ , where  $W_{\overline{y}}$  is the fiber over  $\overline{y}$  of the projection  $\mathbf{M} \times_k Y \to Y$  restricted to W. Since W is open subscheme of  $\mathbf{M} \times_k Y$ , this implies that  $W = \mathbf{M} \times_k Y$  and hence  $\gamma$  factors through j.

As we shall see below both Theorems are extremely useful properties of Białynicki-Birula functors. Now we introduce a formal version of this functor.

**Definition 4.8.** Let **M** be an affine monoid k-scheme with zero **o** and let **G** be its group of units. For every  $n \in \mathbb{N}$  let  $\mathbf{M}_n \hookrightarrow \mathbf{M}$  be an n-th infinitesimal neighborhood of **o** in **M**. Let X be a k-scheme equipped with an action of **G**. For every k-scheme Y we define

$$\widehat{\mathcal{D}}_X(Y) = \left\{ \left\{ \gamma_n : \mathbf{M}_n \times_k Y \to X \right\}_{n \in \mathbb{N}} \middle| \forall_{n \in \mathbb{N}} \gamma_n \text{ is } \mathbf{G}\text{-equivariant and } \gamma_{n+1 \mid \mathbf{M}_n \times_k Y} = \gamma_n \right\}$$

This gives gives rise to a functor  $\widehat{\mathcal{D}}_X$ . We call it the formal Białynicki-Birula functor of X.

**Remark 4.9.** Let **M** be an affine monoid k-scheme with zero **o** and let **G** be its group of units. Let X be a k-scheme equipped with an action of **G**. Then there exists a canonical morphism of functors  $\mathcal{D}_X \to \widehat{\mathcal{D}}_X$  given by

$$\gamma \mapsto \{\gamma_{|\mathbf{M}_n \times_k Y}\}_{n \in \mathbb{N}}$$

for every  $\gamma \in \mathcal{D}_X(Y)$  and every k-scheme Y.

5. Representability of Białynicki-Birula functor for Kempf monoids

In this section we prove various results concerning representability of Białynicki-Birula functors.

**Theorem 5.1.** Let M be an affine monoid k-scheme with open and schematically dense group of units G. Suppose that X is an affine k-scheme equipped with an ation of G. Then  $\mathcal{D}_X$  is representable and  $i_X$  is a closed immersion of k-schemes.

*Proof.* Since X is an affine k-scheme, the action of G on X corresponds to the coaction of k[G] by  $c:\Gamma(X,\mathcal{O}_X)\to k[G]\otimes_k\Gamma(X,\mathcal{O}_X)$ . Note that c is a morphism of k-algebras. By Theorem 3.5 there exists a universal morphism  $q:\Gamma(X,\mathcal{O}_X)\twoheadrightarrow W$  of G-representations into a M-representation. Let  $I\subseteq\Gamma(X,\mathcal{O}_X)$  be the ideal generated by  $\ker(q)$ . Fix f in I. Then

$$f = \sum_{i=1}^{n} g_i \cdot f_i$$

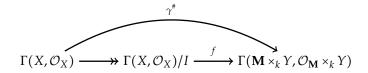

where  $g_i \in k[G]$  and  $f_i \in \ker(q)$  for  $1 \le i \le n$ . Then

$$c(f) = c\left(\sum_{i=1}^{n} g_i \cdot f_i\right) = \sum_{i=1}^{n} c(g_i) \cdot c(f_i) \subseteq \left(k[\mathbf{G}] \otimes_k \Gamma(X, \mathcal{O}_X)\right) \cdot \left(k[\mathbf{G}] \otimes_k \ker(q)\right) \subseteq k[\mathbf{G}] \otimes_k I$$

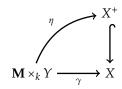

Thus  $c(I) \subseteq k[\mathbf{G}] \otimes_k I$  and hence I is a **G**-representation. Consider

$$X^+ = V(I) = \operatorname{Spec} \Gamma(X, \mathcal{O}_X)/I \longrightarrow X$$

Since  $\Gamma(X, /cO_X)/I$  is the quotient **G**-representation of W, we deduce by Theorem 3.5 that  $\Gamma(X, \mathcal{O}_X)/I$  is a **M**-representation. Hence  $X^+$  is a k-scheme equipped with action of  $\mathbf{M}$  and  $X^+ \hookrightarrow X$  is **G**-equivariant. Suppose now that Y is an affine k-scheme. Then  $\mathbf{M} \times_k Y$  is a **M**-scheme with respect to the left-hand side action of  $\mathbf{M}$  and hence  $\Gamma(\mathbf{M} \times_k Y, \mathcal{O}_{\mathbf{M} \times_k Y})$  is a **M**-representation. Now Theorem 3.5 implies that if  $\gamma : \mathbf{M} \times_k Y \to X$  is a **G**-equivariant morphism, then a morphism  $\gamma^\# : \Gamma(X, \mathcal{O}_X) \to \Gamma(\mathbf{M} \times_k Y, \mathcal{O}_{\mathbf{M} \times_k Y})$  of k-algebras and **G**-representations factors through  $g : \Gamma(X, \mathcal{O}_X) \to W$  and thus by construction of I we have

for some morphism f of k-algebras and G-representations. Since both  $\Gamma(X, \mathcal{O}_X)/I$  and  $\Gamma(\mathbf{M} \times_k Y, \mathcal{O}_{\mathbf{M}} \times_k Y)$  are  $\mathbf{M}$ -representations and by Theorem 3.4 the subcategory  $\mathbf{Rep}(\mathbf{M}) \subseteq \mathbf{Rep}(\mathbf{G})$  is full, we derive that f is a morphism of  $\mathbf{M}$ -representations. Thus f corresponds to a unique  $\mathbf{M}$ -equivariant morphism  $\eta: \mathbf{M} \times_k Y \to X^+$  such that the diagram

is commutative. Now this result can be extended to an arbitrary k-scheme Y, since  $Mor_k(\mathbf{M} \times_k (-), X^+)$  is a Zariski sheaf and a morphism that is  $\mathbf{M}$ -equivariant locally on the domain is  $\mathbf{M}$ -equivariant. Thus for every k-scheme Y we have a bijection

$$\mathcal{D}_X(Y) \ni \gamma \mapsto \eta \in \{\mathbf{M}\text{-equivariant morphisms } \mathbf{M} \times_k Y \to X^+\}$$

Since we also have a bijection

$$\{\mathbf{M}\text{-equivariant morphisms }\mathbf{M}\times_k Y\to X^+\}\ni \eta\mapsto \eta\cdot \langle e,1_{X^+}\rangle\in \mathrm{Mor}_k(Y,X^+)$$

and both this bijections are natural, we derive that  $\mathcal{D}_X$  is represented by  $X^+$  and moreover,  $i_X: \mathcal{D}_X \to X$  is a closed immersion  $X^+ \hookrightarrow X$ .

In order to prove more interesting result we need to recall some fact..

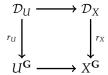

**Remark 5.2.** Let **G** be a geometrically connected and locally algebraic group over k. It follows by [Monygham, 2020c, Theorem 7.2] that for every k-scheme X equipped with an action of **G** there exists closed subscheme  $X^{\mathbf{G}}$  of X representing the fixed point functor.

**Corollary 5.3.** Let G be a geometrically connected and locally algebraic group k-scheme and M be a Kempf monoid having G as a group of units. Suppose that X is a k-scheme equipped with an action of G such that there exists a family U of open affine G-stable open subschemes of X such that

$$X^{\mathbf{G}} \subseteq \bigcup_{U \in \mathcal{U}} U$$

*Then*  $\mathcal{D}_X$  *is representable.* 

*Proof.* Note that **G** is affine group k-scheme as a unit group of an affine monoid **M** ([Monygham, 2020d, Proposition 12.4]). Moreover, **M** is a Kempf monoid and hence **G** is open and schematically dense in **M**. By Theorem 5.1 each  $\mathcal{D}_U$  is representable by a k-scheme. On the other hand by Theorem 4.7 for each  $U \in \mathcal{U}$  we have a cartesian square

of functors. Since both  $U^{\mathbf{G}}$  and  $X^{\mathbf{G}}$  are k-schemes by Remark 5.2, this implies that  $\{\mathcal{D}_U \to \mathcal{D}_X\}_{U \in \mathcal{U}}$  is an open cover of  $\mathcal{D}_X$  as a pullback of an open cover  $\{U^{\mathbf{G}} \to X^{\mathbf{G}}\}_{U \in \mathcal{U}}$ . Hence Fact 4.2 and [Görtz and Wedhorn, 2010, Theorem 8.9] (or if you like [Monygham, 2019, Theorem 4.6]) imply that  $\mathcal{D}_X$  is representable.

**Corollary 5.4.** Let G be a geometrically connected and locally algebraic group k-scheme and M be a Kempf monoid having G as a group of units. Suppose that X is a locally linear G-scheme. Then  $\mathcal{D}_X$  is representable.

*Proof.* This is a consequence of Corollary 5.3.

**Theorem 5.5.** Let G be a geometrically connected and locally algebraic group k-scheme and M be a Kempf monoid having G as a group of units. Suppose that X is a k-scheme equipped with action of G. Then  $\widehat{\mathcal{D}}_X$  is representable.
