### **QUOTIENTS OF ALGEBRAIC GROUPS**

## 1. Introduction

Throughout this notes k denote a field and G denote a group scheme over k. We denote by e the identity of G. We also fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ .

## 2. Basic properties of scheme group quotients

The following result gives scheme-theoretic criterion for topological quotient in the case of group scheme actions.

**Proposition 2.1.** Let Y be a k-scheme with the trivial action of G and let  $q: X \to Y$  be a G-equivariant morphism. Assume that q is submersive and and the morphism  $G \times_k X \to X \times_Y X$  induced by a and  $\operatorname{pr}_X$  is surjective. Then the diagram

$$\mathbf{G} \times_k X \xrightarrow{q} X \xrightarrow{q} Y$$

is a cokernel in the category topological spaces.

*Proof.* Let  $\pi_1$  and  $\pi_2$  be distinct projections  $X \times_Y X \to X$ . Pick points  $x_1$  and  $x_2$  in X such that  $q(x_1) = q(x_2)$ . Then there exists a field extension K over k such that  $k(x_1) \subseteq K$  and  $k(x_2) \subseteq K$ . These give rise to K-points  $\overline{x_1}$  and  $\overline{x_2}$  of X such that their images under q is the same K-point of Y. Since we have an identification

$$(X \times_Y X)(K) = X(K) \times_{Y(K)} X(K)$$

induced by  $\pi_1$  and  $\pi_2$ , we derive that there exists a K-point  $\overline{z}$  of  $X \times_Y X$  such that  $\pi_1(\overline{z}) = \overline{x_1}$  and  $\pi_2(\overline{z}) = \overline{x_2}$ . Let z be the point of  $X \times_Y X$  corresponding to  $\overline{z}$ . Then  $\pi_1(z) = x_1$  and  $\pi_2(z) = x_2$ . By assumption a and  $\operatorname{pr}_X$  induce surjection  $G \times_k X \twoheadrightarrow X \times_Y X$ . Thus there exists a point u of  $G \times_k X$  such that  $a(u) = x_1$  and  $\operatorname{pr}_X(u) = x_2$ . Thus  $x_1$  and  $x_2$  are identified by an equivalence relation on the underlying set of X which is determined by the pair  $(a,\operatorname{pr}_X)$ . Therefore, fibers of q are equivalence classes with respect to this relation. Since q is submersive, this implies that the diagram

$$\mathbf{G} \times_k X \xrightarrow{p_{\mathbf{r}_X}} X \xrightarrow{q} Y$$

is a cokernel in the category topological spaces.

Now we prove a series results concerning fpqc descent. For this we fix a k-scheme Y with the trivial action of G and a G-equivariant morphism  $q: X \to Y$ . Let  $g: Y' \to Y$  be a morphism of k-schemes and consider the cartesian square

$$X' \xrightarrow{g'} X$$

$$\downarrow^{q'} \downarrow^{q} \qquad \downarrow^{q}$$

$$Y' \xrightarrow{g} Y$$

of k-schemes. Note that X' admits a unique action a' of G such that the square above consists of G-equivariant morphism (we consider g as a G-equivariant morphism between trivial G-schemes).

**Fact 2.2.** Suppose that g is faithfully flat and quasi-compact. Assume that g' is (universally) submersive. Then g is (universally) submersive.

*Proof.* It suffices to prove that submersive morphisms have descent property. This follows from the fact that g (as faithfully flat and quasi-compact morphism) and q' are submersive. Details are left for the reader.

**Fact 2.3.** Suppose that g is faithfully flat and quasi-compact. Then the canonical morphism  $X' \times_{Y'} X' \to X \times_Y X$  is faithfully flat and quasi-compact and there is the cartesian square

$$G \times_k X' \longrightarrow G \times_k X$$

$$\downarrow \qquad \qquad \downarrow$$

$$X' \times_{Y'} X' \longrightarrow X \times_Y X$$

in which the left vertical arrow is induced by  $\langle a', \operatorname{pr}_{X'} \rangle : \mathbf{G} \times_k X' \to X' \times_k X'$ , the right vertical arrow is induced by  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \to X \times_k X$  and the bottom horizontal morphism is the canonical morphism.

*Proof.* Note that squares

$$X' \times_{Y'} X' \longrightarrow X' \times_{Y} X'$$

$$\downarrow \qquad \qquad \qquad \qquad \qquad X' \times_{Y} X' \longrightarrow X \times_{Y} X$$

$$\downarrow \qquad \qquad \downarrow \qquad \qquad \downarrow$$

$$Y' \longrightarrow_{g} Y$$

$$X' \times_{k} X' \xrightarrow{g' \times_{k} g'} X \times_{k} X$$

are cartesian. Since both g and  $g' \times_k g'$  are faithfully flat and quasi-compact, we derive that both morphisms  $X' \times_{Y'} X' \to X' \times_Y X'$  and  $X' \times_Y X' \to X \times_Y X$  are faithfully flat and quasi-compact. Then their composition i.e. the canonical morphism  $X' \times_{Y'} X' \to X \times_Y X$  is faithfully flat and quasi-compact.

Finally we need the following notion

**Definition 2.4.** Let *Y* be a *k*-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Consider a pair

$$q_*\mathcal{O}_X \xrightarrow[q_*pr_X^\#]{} q_*\left(\operatorname{pr}_X\right)_* \mathcal{O}_{\mathbf{G}\times_k X} = q_*a_*\mathcal{O}_{\mathbf{G}\times_k X}$$

of morphisms of sheaves of rings on Y. Suppose that  $q^{\#}: \mathcal{O}_{Y} \to q_{*}\mathcal{O}_{X}$  is a kernel of this pair. Then  $\mathcal{O}_{Y}$  is the sheaf of  $\mathbf{G}$ -invariants for q.

**Proposition 2.5.** Suppose that g is faitfully flat and quasi-compact. Assume that q' is quasi-compact, semiseparated and  $\mathcal{O}_{Y'}$  is the sheaf of G-invariants for q'. Then  $\mathcal{O}_{Y}$  is the sheaf of G-invariants for q.

*Proof.* We denote by a' the action of G on X'. First note that q is semiseparated and quasi-compact morphism as these classes of morphisms admit descent along quasi-compact and faithfully flat

morphisms. Since q is quasi-compact, semiseparated and g is flat, we derive that for every quasi-coherent sheaf  $\mathcal F$  on X the canonical morphism  $q'_*g'^*\mathcal F \to g^*q_*\mathcal F$  is an isomorphism. Thus the diagram

$$\mathcal{O}_{Y'} \xrightarrow{q^{\#}} q'_{\star} \mathcal{O}_{X'} \xrightarrow{q'_{\star} a'^{\#} \atop q'_{\star} \operatorname{pr}_{Y'}^{\#}} q'_{\star} \left(\operatorname{pr}_{X'}\right)_{\star} \mathcal{O}_{G \times_{k} X'} = q'_{\star} a'_{\star} \mathcal{O}_{G \times_{k} X'}$$

is isomorphic to the diagram

$$g^*\mathcal{O}_Y \xrightarrow{g^*q^\#} g^*\left(q_*\mathcal{O}_X\right) \xrightarrow{g^*q_*n^\#} g^*\left(q_*\left(\operatorname{pr}_X\right)_*\mathcal{O}_{\mathbf{G}\times_kX}\right) = g^*\left(q_*a_*\mathcal{O}_{\mathbf{G}\times_kX}\right)$$

Since  $\mathcal{O}_{Y'}$  is the sheaf of **G**-invariants for q', the first diagram is a kernel diagram. Hence the second is a kernel diagram. According to the fact that g is faithfully flat we deduce that the diagram

$$\mathcal{O}_{Y} \xrightarrow{q^{\#}} q_{*}\mathcal{O}_{X} \xrightarrow{q_{*}\mathbf{pr}_{Y}^{\#}} q_{*} \left(\mathbf{pr}_{X}\right)_{*} \mathcal{O}_{\mathbf{G}\times_{k}X} = q_{*}a_{*}\mathcal{O}_{\mathbf{G}\times_{k}X}$$

is also a kernel diagram. Thus  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q.

# 3. CATEGORICAL AND GEOMETRIC QUOTIENTS

**Definition 3.1.** Let *Y* be a *k*-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Suppose that the following conditions hold.

- (1) q is submersive.
- (2) The morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by  $\langle a, \operatorname{pr}_x \rangle : \mathbf{G} \times_k X \to X \times_k X$  is surjective.
- (3)  $\mathcal{O}_{Y}$  is the sheaf of **G**-invariant for *q*.

Then *q* is a geometric quotient of *X*.

**Corollary 3.2.** Let q be a geometric quotient of X. Then the diagram

$$\mathbf{G} \times_k X \xrightarrow{p_{\mathbf{r}_X}} X \xrightarrow{q} Y$$

is a cokernel in the category of ringed spaces.

*Proof.* Due to the fact that  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q it suffices to prove that

$$\mathbf{G} \times_k X \xrightarrow{g} X \xrightarrow{q} Y$$

is the cokernel in the category of topological spaces. This follows from Proposition 2.1.

**Definition 3.3.** Let  $q: X \to Y$  be a morphism of k-schemes such that the diagram

$$\mathbf{G} \times_k X \xrightarrow{g} X \xrightarrow{q} Y$$

is a cokernel in the category of k-schemes. Then  $q: X \to Y$  is a categorical quotient of X.

**Fact 3.4.** Every geometric quotient is categorical.

*Proof.* Categorical quotient is a cokernel in the category of k-schemes. On the other hand geometric quotient is a cokernel in the category of locally ringed spaces and hence it also satisfies cokernel property in its full subcategory of k-schemes. Thus every geometric quotient is categorical.

Let  $q: X \to Y$  be a morphism of k-schemes such that  $q \cdot \operatorname{pr}_X = q \cdot a$ . For a morphism  $g: Y' \to Y$  of k-schemes consider the cartesian square

$$X' \xrightarrow{g'} X$$

$$q' \downarrow \qquad \qquad \downarrow q$$

$$Y' \xrightarrow{g} Y$$

Then there exists a unique action  $a' : \mathbf{G} \times_k X' \to X'$  of  $\mathbf{G}$  on X' such that the square above consists of  $\mathbf{G}$ -equivariant morphism (we consider Y, Y' as  $\mathbf{G}$ -schemes equipped with trivial  $\mathbf{G}$ -actions). Keeping this in mind we have the following.

**Definition 3.5.** A morphism  $q: X \to Y$  is a uniform categorical (geometric) quotient of X if for every flat morphism  $g: Y' \to Y$  its base change  $q': X' \to Y'$  is a categorical (geometric) quotient of X'.

**Definition 3.6.** A morphism  $q: X \to Y$  is a universal categorical (geometric) quotient of X if for every morphism  $g: Y' \to Y$  its base change  $q': X' \to Y'$  is a categorical (geometric) quotient of X'.

**Corollary 3.7.** Let  $g: Y' \to Y$  be a faithfully flat and quasi-compact morphism. Suppose that q' is a geometric quotient, then q is a geometric quotient.

*Proof.* This follows from Facts 2.2, 2.3 and Proposition 2.5.

In the next result we give a simple example of a universal geometric quotient.

**Proposition 3.8.** Suppose that **G** is a quasi-compact group scheme over k. Let Y be a k-scheme and consider  $\mathbf{G} \times_k Y$  with the action of **G** induced by the regular action on the left factor. Then  $\operatorname{pr}_Y : \mathbf{G} \times_k Y \to Y$  is a universal geometric quotient.

*Proof.* Clearly  $\operatorname{pr}_Y$  is univerally submersive (it is even universally open). Let  $\mu: \mathbf{G} \times_k \mathbf{G} \to \mathbf{G}$  be the multiplication morphism and let  $\pi_{23}: \mathbf{G} \times_k \mathbf{G} \times Y \to \mathbf{G} \times_k Y$  be the projection on the last two factors. Then the morphism

$$\mathbf{G} \times_k \mathbf{G} \times_k \Upsilon \to (\mathbf{G} \times_k \Upsilon) \times_{\Upsilon} (\mathbf{G} \times_k \Upsilon) = \mathbf{G} \times_k \mathbf{G} \times_k \Upsilon$$

induced by  $\langle \mu \times_k 1_Y, \pi_{23} \rangle : \mathbf{G} \times_k \mathbf{G} \times_k Y \to (\mathbf{G} \times_k Y) \times_k (\mathbf{G} \times_k Y)$  is an isomorphism. We show that  $\mathcal{O}_Y$  is the sheaf of  $\mathbf{G}$ -invariants for  $\mathrm{pr}_Y$ . For this pick an affine open subset V of Y. It suffices to check that the diagram

$$\Gamma(V, \mathcal{O}_{Y}) \xrightarrow{\operatorname{pr}_{Y}^{\#}} \Gamma\left(\mathbf{G} \times_{k} V, \mathcal{O}_{\mathbf{G} \times_{k} Y}\right) \xrightarrow{\left(\mu \times_{k} 1_{Y}\right)^{\#}} \Gamma\left(\mathbf{G} \times_{k} \mathbf{G} \times_{k} V, \mathcal{O}_{\mathbf{G} \times_{k} \mathbf{G} \times_{k} Y}\right)$$

is a kernel. Since G is quasi-compact and separated (every group k-scheme is separated), we derive that the diagram above is isomorphic with

$$\Gamma(V, \mathcal{O}_{Y}) \xrightarrow{f \mapsto 1 \otimes f} \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) \otimes_{k} \Gamma(V, \mathcal{O}_{Y}) \xrightarrow{\underset{\chi \otimes f \mapsto 1 \otimes \chi \otimes f}{\chi \otimes f \mapsto 1 \otimes \chi \otimes f}} \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) \otimes_{k} \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) \otimes_{k} \Gamma(V, \mathcal{O}_{Y})$$

Thus the first diagram is the kernel diagram if  $f \mapsto 1 \otimes f$  induces an isomorphism of  $\Gamma(V, \mathcal{O}_Y)$  with subspace of  $\Gamma(G, \mathcal{O}_G) \otimes_k \Gamma(V, \mathcal{O}_Y)$  given by formula

$$\{\chi \in \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) | \mu^{\#}(\chi) = 1 \otimes \chi\} \otimes_{k} \Gamma(V, \mathcal{O}_{Y})$$

Hence it suffices to prove that

$$\{\chi \in \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) | \mu^{\#}(\chi) = 1 \otimes \chi\} = \text{constant functions on } \mathbf{G}$$

For this pick a k-algebra A and let  $g: \operatorname{Spec} A \to \mathbf{G}$  be an A-point. Next let  $e: \operatorname{Spec} A \to \mathbf{G}$  be an A-point of  $\mathbf{G}$  which corresponds to the identity element of  $\mathbf{G}$ . Suppose that a regular function  $\chi$  in  $\mathbf{G}$  satisfies  $\mu^{\#}(\chi) = 1 \otimes \chi$ . Then

$$g^{\#}(\chi) = \langle g, e \rangle^{\#} \mu^{\#}(\chi) = \langle g, e \rangle^{\#} (1 \otimes \chi) = e^{\#}(\chi)$$

Recall that e is given by the composition of the structural morphism  $\operatorname{Spec} A \to \operatorname{Spec} k$  and the k-point  $\operatorname{Spec} k \to \mathbf{G}$  determined by the identity of  $\mathbf{G}$ . Thus  $g^{\#}(\chi)$  is an element of k. Since this follows for every  $g:\operatorname{Spec} A \to \mathbf{G}$ , we derive that  $\chi$  is a constant function. This completes the proof of our claim that

$$\Gamma(V, \mathcal{O}_{Y}) \xrightarrow{\operatorname{pr}_{Y}^{\#}} \Gamma\left(\mathbf{G} \times_{k} V, \mathcal{O}_{\mathbf{G} \times_{k} Y}\right) \xrightarrow{\left(\mu \times_{k} 1_{Y}\right)^{\#}} \Gamma\left(\mathbf{G} \times_{k} \mathbf{G} \times_{k} V, \mathcal{O}_{\mathbf{G} \times_{k} \mathbf{G} \times_{k} Y}\right)$$

is the kernel diagram and hence  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for  $\operatorname{pr}_Y$ . Therefore, we proved that  $\operatorname{pr}_Y$  is a geometric quotient of  $\mathbf{G} \times_k Y$ . Consider any morphism  $Y' \to Y$ . Then base change of  $\operatorname{pr}_Y$  along this morphism is  $\operatorname{pr}_{Y'}$ . We conclude that  $\operatorname{pr}_Y$  is a universal geometric quotient for  $\mathbf{G} \times_k Y$ .

# 4. Geometric quotients of separated actions

**Definition 4.1.** The action of **G** on *X* is *separated* if the morphism  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \to X \times_k X$  has closed set-theoretic image.

**Theorem 4.2.** Let  $q: X \to Y$  be a geometric quotient of X. Assume that q is universally submersive. Then the following assertions are equivalent.

- (i) The action of G on X is separated.
- (ii) Y is separated.

*Proof.* We have a cartesian square

$$\begin{array}{cccc}
X \times_{Y} X & & & & X \times_{k} X \\
\downarrow & & & & \downarrow q \times_{k} q \\
Y & & & & & Y \times_{k} Y
\end{array}$$

It follows that  $X \times_Y X \hookrightarrow X \times_k X$  is a locally closed immersion. Since q is a geometric quotient, we derive that  $\langle a, \operatorname{pr}_X \rangle$  factors as a surjective morphism  $\mathbf{G} \times_k X \twoheadrightarrow X \times_Y X$  followed by the immersion  $X \times_Y X \hookrightarrow X \times_k X$ . Thus the action of  $\mathbf{G}$  on X is separated if and only if  $X \times_Y X$  is a closed subscheme of  $X \times_k X$ . Since q is universally submersive, we derive that  $q \times_k q$  is submersive. As

the square above is cartesian we derive that  $\Delta_Y(Y) \subseteq Y \times_k Y$  is closed if and only if  $X \times_Y X \subseteq X \times_k X$  is closed. Therefore, Y is separated if and only if the action of G on X is separated.

## 5. GEOMETRIC QUOTIENTS OF FREE ACTIONS AND PRINCIPAL BUNDLES

**Definition 5.1.** The action of **G** on *X* is *free* if the morphism  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \to X \times_k X$  is a closed immersion.

**Definition 5.2.** Let x be a k-point of X. Suppose that the orbit morphism  $\mathbf{G} \to X$  of x given by the composition

$$\mathbf{G} = \mathbf{G} \times_k \operatorname{Spec} k \xrightarrow{\operatorname{induced} \operatorname{by} x} \mathbf{G} \times_k X \longrightarrow X$$

is a closed immersion. Then the action of G on X has a closed free orbit at x.

**Fact 5.3.** *If the action of* G *on* X *is free, then every k-point of* X *has a closed free orbit.* 

The following result states that over special type of local complete noetherian *k*-algebras geometric quotients of free actions correspond to trivial **G**-bundles.

**Theorem 5.4.** Suppose that k is an algebraically closed field and G is a smooth algebraic group over k. Let  $q: X \to Y$  be a geometric quotient locally of finite type and let Y be the spectrum of a complete local noetherian k-algebra such that the residue field of the closed point of Y is k. Then the following assertions hold.

(1) If x is a k-point of X which has a closed free orbit, then there exists a G-equivariant, étale and surjective morphism  $f: G \times_k Y \to X$  such that the triangle

is commutative and the morphism

$$Y = \operatorname{Spec} k \times_k Y \xrightarrow{e \times_k 1_Y} \mathbf{G} \times_k Y \xrightarrow{f} X$$

is a section of q.

**(2)** If the action of G on X is free, then f is an isomorphism.

The proof relies on two algebraic lemmas. The first describe free actions in context of complete rings (it is [Mumford et al., 1994, lemma on page 18]) and the second is a version of Hensel's lemma.

**Lemma 5.4.1.** Let  $(R, \mathfrak{m}, k)$  be a complete local noetherian k-algebra and let  $\sigma : R \to R[[x_1, ..., x_n]]$  be a local morphism into a ring of formal power series over R. Assume that the composition

$$R \xrightarrow{\sigma} R[[x_1,...,x_n]] \xrightarrow{f \mapsto f \operatorname{mod}(x_1,...,x_n)} R$$

is the identity and the composition

$$R \xrightarrow{\sigma} R[[x_1, ..., x_n]] \xrightarrow{f \mapsto f \bmod \mathfrak{m}} (R/\mathfrak{m})[[x_1, ..., x_n]] = k[[x_1, ..., x_n]]$$

is surjective. Consider elements  $y_1,...,y_n$  of R such that  $\sigma(y_i) \mod \mathfrak{m} = x_i$  for i = 1,...,n. Then the composition

$$R \xrightarrow{\sigma} R[[x_1,...,x_n]] \xrightarrow{f \mapsto f \operatorname{mod}(y_1,...,y_n)} (R/(y_1,...,y_n))[[x_1,...,x_n]]$$

is an isomorphism.

*Proof of the lemma.* For convienience let  $\phi$  denote the morphism given by the rule  $r \mapsto \sigma(r) \mod (y_1, ..., y_n)$ . Also denote  $R/(y_1, ..., y_n)$  by S. According to assumptions we have

$$\sigma(y_i) = x_i + y_i + \sum_{j=1}^n x_j \cdot \mathfrak{m}[[x_1, ..., x_n]]$$

for each i. Thus  $\phi(y_i) = \sum_{j=1}^n f_{ij} \cdot x_j$  where  $f_{ij} \in S$  are elements such that the matrix  $[f_{ij}]_{1 \le i,j \le n}$  is invertible in S. Hence

$$S[[x_1,...,x_n]] = S[[\phi(y_1),...,\phi(y_n)]]$$

and  $\phi$  composed with  $S[[\phi(y_1),...,\phi(y_n)]] \twoheadrightarrow S$  is the quotient morphism  $R \twoheadrightarrow S$ . From this observations we derive that  $\phi$  is surjective. It remains to prove that it is injective. Consider z in R such that  $\phi(z) = 0$ . Suppose that  $z \in (y_1,...,y_n)^m$  for some  $m \in \mathbb{N}$ . Write

$$z = \sum_{\alpha \in \Lambda} c_{\alpha} \cdot y_1^{\alpha_1} ... y_n^{\alpha_n}$$

for some  $c_{\alpha} \in R$  where  $\Lambda = \{\alpha \in \mathbb{N}^n \mid \alpha_1 + ... + \alpha_n = m\}$ . Hence

$$0 = \phi(z) = \sum_{\alpha \in \Lambda} \phi(c_{\alpha}) \cdot \phi(y_{1})^{\alpha_{1}} ... \phi(y_{n})^{\alpha_{n}}$$

Thus  $\phi(c_{\alpha}) \in (\phi(y_1),...,\phi(y_n))$  for every  $\alpha \in \Lambda$ . Since  $\phi$  composed with  $S[[\phi(y_1),...,\phi(y_n)]] \twoheadrightarrow S$  is the quotient morphism  $R \twoheadrightarrow S$ , we derive that

$$c_{\alpha} \mod (y_1, ..., y_n) = \phi(c_{\alpha}) \mod (\phi(y_1), ..., \phi(y_n)) = 0$$

for every  $\alpha \in \Lambda$ . Thus  $c_{\alpha} \in (y_1, ..., y_n)$  for every  $\alpha \in \Lambda$ , which implies that  $z \in (y_1, ..., y_n)^{m+1}$ . Thus we proved that

$$\phi(z) = 0 \text{ and } z \in (y_1, ..., y_n)^m \Rightarrow z \in (y_1, ..., y_n)^{m+1}$$

By m-adic completeness of R this implies that  $\phi(z)=0$  if and only if z=0. Hence  $\phi$  is also injective.

**Lemma 5.4.2.** Let  $(R, \mathfrak{m})$  be a complete local noetherian ring and let  $R \to S$  be a local morphism into a local noetherian ring. Suppose that there exists a finitely generated R-submodule R of R such that

$$S = N + mS$$

Then S = N.

*Proof of the lemma.* Pick s in S. Since  $S = N + \mathfrak{m}S$ , there exists a sequence  $\{x_n\}_{n \in \mathbb{N}}$  such that  $x_n \in \mathfrak{m}^n N$  and

$$s - \sum_{i < n} x_i \in \mathfrak{m}^{n+1} S$$

According to the assumption that  $(R, \mathfrak{m})$  is complete with respect to  $\mathfrak{m}$ -adic topology and N is finitely generated over R, we deduce that N is complete with respect to  $\mathfrak{m}$ -adic topology. Hence there exists a unique element x in N such that

$$x = \sum_{n \in \mathbb{N}} x_n$$

where above series is convergent with respect to m-adic topology. Note also that

$$x - \sum_{i < n} x_i \in \mathfrak{m}^{n+1} N$$

for every  $n \in \mathbb{N}$ . Thus we have

$$s - x = \left(s - \sum_{i \le n} x_i\right) - \left(x - \sum_{i \le n} x_i\right) \in \mathfrak{m}^{n+1}S + \mathfrak{m}^{n+1}N = \mathfrak{m}^{n+1}S$$

for every  $n \in \mathbb{N}$ . Hence

$$x - s \in \bigcap_{n \in \mathbb{N}} \mathfrak{m}^n S$$

Since  $R \to S$  is local morphism and S is a local ring, we deduce that  $\mathfrak{m}S$  is contained in the maximal ideal of S. By assumptions S is noetherian. Therefore, S is separated with respect to  $\mathfrak{m}$ -adic topology. This implies that

$$0 = \bigcap_{n \in \mathbb{N}} \mathfrak{m}^n S$$

Thus s - x = 0 and we infer that s is an element of N. This completes the proof that S = N.  $\square$ 

In what follows we shall denote by Gx the closed subscheme determined by the orbit morphism  $G \to X$  of a k-point x of X which has a closed free orbit. For readers convienience we include the following lemmas, which have topological content.

**Lemma 5.4.3.** Let  $q: X \to Y$  be a geometric quotient and assume that Y is the spectrum of a local k-algebra such that the residue field of the closed point o of Y is k. Let x be a k-point of X with free closed orbit, then  $q^{-1}(o) = \mathbf{G}x$  as closed subschemes of X.

*Proof of the lemma.* Morphism q induces the morphism of residue fields  $k(q(x)) \hookrightarrow k(x) = k$  over k. This implies that k(q(x)) = k and hence q(x) is a k-point of Y. Note that o is the unique k-point of Y. Thus q(x) = o. Clearly  $q^{-1}(o)$  is a closed G-stable subscheme of X (it is the preimage of o under G-equivariant q), that contains x. Since G is the smallest closed G-stable subscheme of X containing x, we deduce that  $Gx \subseteq q^{-1}(o)$  scheme-theoretically. Consider the pair of arrows

$$\mathbf{G} \times_k X \xrightarrow{pr_X} X$$

Passing to functors of points we obtain that  $a^{-1}(\mathbf{G}x) = \operatorname{pr}_X(\mathbf{G}.x)$ . Since q is the cokernel of the pair  $(a,\operatorname{pr}_X)$  in the category of topological spaces, we deduce that there exists a closed subset Z of Y such that  $q^{-1}(Z) = \mathbf{G}x$ . Clearly  $o \in Z$  and hence  $q^{-1}(o) \subseteq \mathbf{G}x$  set-theoretically. On the other hand above we proved that  $\mathbf{G}x \subseteq q^{-1}(o)$  scheme-theoretically. This can only happen if  $q^{-1}(o) = \mathbf{G}x$  as closed subschemes of X.

**Lemma 5.4.4.** Let  $q: X \to Y$  be a geometric quotient and assume that Y is the spectrum of a local kalgebra such that the residue field of the closed point o of Y is k. Let U be an open **G**-stable subset of X which contain a k-point. Then U = X.

Proof of the lemma. Consider the pair of arrows

$$\mathbf{G} \times_k X \xrightarrow{pr_X} X$$

Since U is **G**-stable open subset of X, we derive that  $\operatorname{pr}_X^{-1}(U) = a^{-1}(U)$ . Next by definition q is the cokernel of the above pair in the category of topological spaces. Hence there exists an open subset V of Y such that  $U = q^{-1}(V)$ . Since U contains a k-point of X, we deduce as in Lemma 5.4.3 that  $o \in V$ . Thus V = Y and finally  $U = q^{-1}(V) = X$ .

*Proof of the theorem.* We first prove **(1)**. Denote by o the closed point of Y. Assume that x is a k-point of X which has a closed free orbit. Consider the surjective morphism  $\mathcal{O}_{X,x} \twoheadrightarrow \mathcal{O}_{G,e}$  induced by the orbit morphism  $G \hookrightarrow X$  of x. Since G is smooth over k, the ring  $\mathcal{O}_{G,e}$  is regular. Pick a system of parameters  $x_1,...,x_n$  of  $\mathcal{O}_{G,e}$  and let  $y_1,...,y_n$  be elements of  $\mathcal{O}_{X,x}$  such that  $y_i$  is send to  $x_i$  by the morphism  $\mathcal{O}_{X,x} \twoheadrightarrow \mathcal{O}_{G,e}$  for  $1 \le i \le n$ . Define S to be the quotient ring  $\mathcal{O}_{X,x}/(y_1,...,y_n)$ . The morphism q induces the morphism  $q^\#: \mathcal{O}_{Y,o} \to \mathcal{O}_{X,x}$  and hence the morphism  $\mathcal{O}_{Y,o} \to S$ . By Lemma 5.4.3 we have

$$S/\mathfrak{m}_{o}S = k$$

where  $\mathfrak{m}_o$  is the maximal ideal of  $\mathcal{O}_{Y,o}$ . According to Lemma 5.4.2 we derive that  $\mathcal{O}_{Y,o} \to S$  is surjective. Let  $f: \mathbf{G} \times_k \operatorname{Spec} S \to X$  be the unique  $\mathbf{G}$ -equivariant morphism induced by the surjection  $\mathcal{O}_{X,x} \twoheadrightarrow S$ . We have a commutative square

$$G \times_k \operatorname{Spec} S \xrightarrow{f} X$$

$$\operatorname{pr}_{\operatorname{Spec} S} \downarrow \qquad \qquad \downarrow q$$

$$\operatorname{Spec} S \xrightarrow{i} Y$$

where j is a closed immersion induced by  $\mathcal{O}_{Y,o} \twoheadrightarrow S$ . According to assumptions q is locally of finite type. Moreover, G is an algebraic group over k and hence  $\operatorname{pr}_{\operatorname{Spec} S}$  is locally of finite type. These two assertions together with the fact that  $\operatorname{Spec} S \hookrightarrow Y$  is a closed immersion of noetherian schemes (and thus is of finite type) imply that f is locally of finite type. Then by Lemma 5.4.1 we deduce that f induces an isomorphism

$$\widehat{\mathcal{O}_{X,x}} \longrightarrow \widehat{S}[[x_1,...,x_n]] = \widehat{S} \hat{\otimes}_k \widehat{\mathcal{O}_{G,e}}$$

of complete local rings. Since f is locally of finite type, it follows that f is étale at a k-point of  $\mathbf{G} \times_k \operatorname{Spec} S$  determined by the unique k-point of  $\operatorname{Spec} S$  and  $e \in \mathbf{G}$ . Let U be an étale locus of f. It contains a k-point and hence it is nonempty. Moreover, U is open (it is étale locus) subset of X. Since f is  $\mathbf{G}$ -equivariant, we derive that U is  $\mathbf{G}$ -stable. Similarly f(U) is open  $\mathbf{G}$ -stable subset of X and  $X \in f(U)$ . Thus by Lemma 5.4.4 we deduce that

$$U = \mathbf{G} \times_k \operatorname{Spec} S, f(U) = X$$

Therefore, f is étale and surjective. Now we pullback  $g: X \to Y$  along the closed immersion Spec  $S \hookrightarrow Y$ . We obtain a cartesian square

$$\tilde{X} \stackrel{\tilde{j}}{\longleftarrow} X \\
\downarrow^{\tilde{q}} \qquad \qquad \downarrow^{q} \\
\operatorname{Spec} S \stackrel{\tilde{j}}{\longleftarrow} Y$$

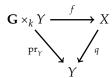

Then f factors as a morphism  $\mathbf{G} \times_k \operatorname{Spec} S \to \tilde{X}$  followed by a closed immersion  $\tilde{f}$ . Since f is étale and surjective, we deduce that  $\tilde{f}$  is étale and surjective. This implies that  $\tilde{f}$  is an isomorphism of schemes. By definition of geometric quotient we derive that the diagram

$$\mathcal{O}_{Y} \xrightarrow{q^{\#}} q_{*}\mathcal{O}_{X} \xrightarrow{q_{*}pr_{*}^{\#}} q_{*} \left(\operatorname{pr}_{X}\right)_{*} \mathcal{O}_{\mathbf{G}\times_{k}X} = q_{*}a_{*}\mathcal{O}_{\mathbf{G}\times_{k}X}$$

is the kernel in the category of sheaves on Y. Hence  $q^{\#}: \mathcal{O}_{Y} \to q_{*}\mathcal{O}_{X}$  is a monomorphism of sheaves. On the other hand we have

$$q^\# = j_* q_* \left(\tilde{j}^{-1}\right)^\# \cdot j_* \tilde{q}^\# \cdot j^\#$$

and thus  $j^{\#}$  is a monomorphism. Since j is a closed immersion, we infer that j is an isomorphism. Therefore, we can identify Spec S with Y. Then f is a morphism which makes the triangle

commutative. This completes the proof of (1).

For the proof of (2) consider the section  $s: Y \hookrightarrow X$  described in (1). Then f fits into a cartesian square

$$\mathbf{G} \times_{k} Y \xrightarrow{f} X \times_{Y} Y = X$$

$$\downarrow_{1_{G} \times_{Y} s} \qquad \downarrow_{1_{X} \times_{Y} s}$$

$$\mathbf{G} \times_{k} X \xrightarrow{\phi} X \times_{Y} X$$

where  $\phi$  is a closed immersion induced by the closed immersion  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \hookrightarrow X \times_k X$  (the action of  $\mathbf{G}$  on X is free). Thus f is a closed immersion. By (1) it is étale and surjective. Therefore, f is an isomorphism.

Remark 5.5. We expect that Theorem 5.4 holds for prime spectra of strictly henselian rings.

Now we introduce sufficient condition for smoothness of geometric quotient in case of locally algebraic *k*-schemes.

**Corollary 5.6.** Suppose that **G** is a smooth algebraic group over k. Let  $q: X \to Y$  be a morphism of finite type between k-schemes locally of finite type. Assume that q is a uniform geometric quotient of X and x is a k-point of X with closed free orbit. Then q is smooth at x.

*Proof.* Since smoothness descent along faithfully flat morphisms, we may assume that k is algebraically closed. Let y = q(x). Then y is a k-point of Y. Now  $1_{\text{Spec }\widehat{\mathcal{O}_{Y,y}}} \times_k q$  is a geometric quotient and  $\widehat{\mathcal{O}_{Y,y}}$  is a complete local noetherian k-algebra with k as a residue field. Moreover, x is a k-point of  $\text{Spec }\widehat{\mathcal{O}_{Y,y}} \times_k X$  with a closed free orbit. By Theorem 5.4 we deduce that  $1_{\text{Spec }\widehat{\mathcal{O}_{Y,y}}} \times_k q$  is smooth. From descent for smoothness we infer that q is smooth at x.

**Definition 5.7.** Let  $q: X \to Y$  be a **G**-equivariant morphism into a k-scheme Y equipped with the trivial **G**-action. Suppose that q is faithfully flat, quasi-compact morphism and the square

$$G \times_k X \xrightarrow{a} X$$

$$pr_X \downarrow \qquad \qquad \downarrow q$$

$$X \xrightarrow{q} Y$$

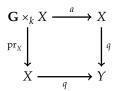

is cartesian. Then *q* is a principal **G**-bundle.

Now we use Theorem 5.4 to describe principal **G**-bundles in the category of locally algebraic k-schemes.

**Theorem 5.8.** Suppose that **G** is a smooth algebraic group over k. Let  $q: X \to Y$  be a morphism of finite type between k-schemes locally of finite type. Then the following assertions are equivalent.

- (i) q is a universal geometric quotient and the action of G on X is free.
- (ii) q is a uniform geometric quotient and the action of G on X is free.
- (iii) q is a principal **G**-bundle.

*Proof.* Clearly (i)  $\Rightarrow$  (ii). Suppose that (ii) holds. Let  $\bar{k}$  be an algebraic closure of k. Then  $1_{\text{Spec}\bar{k}} \times_k q$ is a uniform quotient and the action of Spec  $\overline{k} \times_k \mathbf{G}$  on Spec  $\overline{k} \times_k X$  induced by the action of  $\mathbf{G}$  on *X* is free. Moreover, if  $1_{\text{Spec}\bar{k}} \times_k q$  is a principal  $\text{Spec}\bar{k} \times_k \mathbf{G}$ -bundle, then q is a  $\mathbf{G}$ -bundle. This follows from the observation that property of being a principal bundle descents along faithfuly flat and quasi-compact base extensions. Thus we may assume that k is algebraically closed. Next we pick a k-point y of Y and consider base change  $1_{\text{Spec }\widehat{\mathcal{O}_{Y,y}}} \times_Y q$ . This is a geometric quotient (because morphism Spec  $\widehat{\mathcal{O}_{Y,y}} \to Y$  is flat) and a morphism of finite type. Moreover, the action of **G** on Spec  $\mathcal{O}_{Y,y} \times_Y X$  is free. Since  $\mathcal{O}_{Y,y}$  is a complete noetherian k-algebra with residue field k, we derive by Theorem 5.4 that Spec  $\widehat{\mathcal{O}_{Y,y}} \times_Y q$  is isomorphic as a **G**-equivariant morphism with  $\operatorname{pr}_{\operatorname{Spec} \widetilde{\mathcal{O}_{Y,y}}}$ . By faithfuly flat descent for flat morphism we deduce that q is flat at every point in the fiber  $q^{-1}$  (Spec  $\mathcal{O}_{Y,y}$ ). Since y is an arbitrary k-point, it follows that q is flat at every point of X which specializes to a k-point. Every point of X is a generization of a k-point (X is locally of finite type and k is algebraically closed). Thus q is flat. It is also surjective (as it is a geometric quotient) and quasi-compact (it is of finite type). Therefore, it is faithfully flat and quasi-compact morphism. In order to obtain (iii) it remains to prove that the morphism  $\Phi : \mathbf{G} \times_k X \to X \times_Y X$ induced by a and  $\operatorname{pr}_X$  is an isomorphism. Note that it is a closed immersion (the action of  $\mathbf{G}$  on X is closed). Moreover,  $1_{\operatorname{Spec} \overline{\mathcal{O}_{Y,y}}} \times_Y \Phi$  is an isomorphism due to the fact that  $1_{\operatorname{Spec} \overline{\mathcal{O}_{Y,y}}} \times_Y q$  is isomorphic as a  $\mathbf{G}$ -equivariant morphism with  $\operatorname{pr}_{\operatorname{Spec} \overline{\mathcal{O}_{Y,y}}}$ . By faithfully flat descent we infer that  $1_{\text{Spec }\mathcal{O}_{Y,y}} \times_Y \Phi$  is an isomorphism. This holds for every k-point y in Y. Thus  $\Phi$  induces an isomorphism  $\mathcal{O}_{X\times_Y X,\Phi(z)} \to \mathcal{O}_{G\times_k X,z}$  for every k-point z of  $X\times_Y X$ . Hence a closed immersion  $\Phi$ is an isomorphism. This completes the proof of (ii)  $\Rightarrow$  (iii). Assume now that (iii) holds. Then the square

is cartesian and q is faithfully flat and quasi-compact. By Proposition 3.8 morphism  $\operatorname{pr}_X$  is a universal geometric quotient. According to Corollary 3.7 we derive that q is universal geometric quotient. Moreover, the cartesian square above shows that the morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by a and  $\operatorname{pr}_X$  is an isomorphism. Thus the action of  $\mathbf{G}$  on X is free. This is (i). Hence (iii)  $\Rightarrow$  (i) holds.

### 6. Nagata's theorem

We start by proving the following result which give yet another characterization of linearly reductive groups.

**Theorem 6.1.** Let **G** be a smooth affine algebraic group over k. Then the following assertions are equivalent.

- (i) **G** is linearly reductive.
- (ii) For every finitely dimensional linear representation V of G and for every nonzero G-invariant element v in V there exists a G-invariant linear function  $f: V \to k$  such that  $f(v) \neq 0$ .

We need the following easy result.

**Lemma 6.1.1.** Let G be an algebraic group over k which satisfies (ii). Suppose that V is a finitely dimensional representation of G. Then the map

$$\operatorname{Hom}_{k}(V,k)^{\mathbf{G}}\ni f\mapsto f_{|V^{\mathbf{G}}}\in \operatorname{Hom}_{k}(V^{\mathbf{G}},k)$$

is an isomorphism of vector spaces over k.

*Proof of the lemma.* The image of the map in the statement is a k-vector subspace  $W \subseteq \operatorname{Hom}_k\left(V^{\mathbf{G}},k\right)$  such that for every nonzero element v in  $V^{\mathbf{G}}$  there exists f in W such that  $f(v) \neq 0$  (this is a consequence of (ii)). It follows that W cannot be proper subspace of  $\operatorname{Hom}_k\left(V^{\mathbf{G}},k\right)$ . Hence the map in the statement is an epimorphism. Now fix a nonzero  $\mathbf{G}$ -invariant linear function  $f:V \to k$ . By (ii) there exists a  $\mathbf{G}$ -invariant linear function  $w:\operatorname{Hom}_k\left(V,k\right) \to k$  such that w(f)=0. Note that the canonical isomorphism

$$V \cong \operatorname{Hom}_{k}(\operatorname{Hom}_{k}(V,k),k)$$

of k-vector spaces is a morphism of representations of  $\mathbf{G}$ . Thus w is defined in terms of evaluation in some  $\mathbf{G}$ -invariant vector v in V. Therefore,  $f(v) \neq 0$  and hence  $f_{|V|} \neq 0$ . Thus the map described in the statement is also a monomorphism.

*Proof of the theorem.* Suppose that (i) holds. Consider a **G**-invariant nonzero vector v in a finitely dimensional representation V of **G**. Then  $k \cdot v \subseteq V$  is a **G**-subrepresentation. Since **G** is linearly reductive, there exists a morphism of **G**-representations which is a left inverse of  $k \cdot v \hookrightarrow V$ . This morphism can be identified with a **G**-invariant linear function  $f: V \to k$  such that  $f(v) \neq 0$ . Hence (i)  $\Rightarrow$  (ii).

Now suppose that **(ii)** holds. Pick an epimorphism  $\theta: V \twoheadrightarrow W$  of finitely dimensional representations V of G. Assume that there exists a nonzero G-invariant vector w in W such that  $w \notin \theta(V^G)$ . By Lemma 6.1.1 there exists f in  $\operatorname{Hom}_k(W,k)^G$  such that  $f_{|\theta(V^G)} = 0$  and  $f(w) \neq 0$ . Then  $f \cdot \theta$  is a nonzero element of  $\operatorname{Hom}(V,k)^G$  such that  $(f \cdot \theta)_{|V^G} = 0$ . This is impossible according to Lemma 6.1.1. Hence  $\theta^G: V^G \to W^G$  is an epimorphism. Now assume that  $\theta: V \twoheadrightarrow W$  is an epimorphism of arbitrary linear representations of G. Since G is affine, every linear representation of G is rational (i.e. it is a sum of its finitely dimensional subrepresentations). This together with the finitely dimensional case considered above imply that  $\theta^G: V^G \to W^G$  is an epimorphism. Thus the functor  $(-)^G: \operatorname{Rep}(G) \to \operatorname{Vect}_k$  is exact.

The result above motivates the following notion.

**Definition 6.2.** Let **G** be a smooth affine algebraic group. Suppose that for every finitely dimensional representation V of **G** and for every nonzero **G**-invariant vector v of V there exists a homogenous **G**-invariant polynomial  $f: V \to k$  such that  $f(v) \neq 0$ . Then **G** is *geometrically reductive*.

We state here the following celebrated result.

**Theorem 6.3.** *If* **G** *is reductive, then it is geometrically reductive.* 

The result above is due to Haboush and its proof can be found in [Haboush, 1975]. The following theorem shows that geometric reductivity admits up to an integral extension the same property as linear reductivity (see also Remark 6.5 below).

**Theorem 6.4.** Suppose that **G** is geometrically reductive. Let A be a k-algebra such that Spec A admits an action of **G** and let  $\mathfrak{a}$  be a **G**-stable ideal of A. We consider  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap \mathfrak{a}$  as a k-subalgebra of  $(A/\mathfrak{a})^{\mathbf{G}}$  by means of the canonical inclusion  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap \mathfrak{a} \hookrightarrow A/\mathfrak{a}$ . For every element  $x \in (A/\mathfrak{a})^{\mathbf{G}}$  there exists positive integer r such that  $x^r \in A^{\mathbf{G}}/A^{\mathbf{G}} \cap \mathfrak{a}$ .

*Proof.* Let  $d: A \to k[\mathbf{G}] \otimes_k A$  be the coaction of  $\mathbf{G}$  on A. Pick an element  $x_0 \in A$  which maps to x modulo  $\mathfrak{a}$ . Consider finitely dimensional vector subspace  $V \subseteq A$  over k such that V is a  $\mathbf{G}$ -subrepresentation of A and  $x_0 \in V$ . Since x is  $x_0$  modulo  $\mathfrak{a}$ , we derive that  $c(x_0) - 1 \otimes x_0$  is in ideal of  $k[\mathbf{G}] \otimes_k A$  generated by  $k[\mathbf{G}] \otimes_k \mathfrak{a}$ . Thus  $W = k \cdot x_0 + V \cap \mathfrak{a} \subseteq A$  is finitely dimensional  $\mathbf{G}$ -subrepresentation of A. Let  $\lambda: W \to k$  be a k-linear form such that  $\lambda(x_0) = 1$  and  $\lambda_{|V \cap \mathfrak{a}} = 0$ . Since  $\mathbf{G}$  is geometrically reductive there exists  $f \in \operatorname{Sym}_r(W)^{\mathbf{G}}$  such that  $f(\lambda) = 1$ . Since the canonical morphism  $\operatorname{Sym}_r(W) \to A$  is a morphism of representations of  $\mathbf{G}$ , we deduce that f is mapped under this morphism to some  $\mathbf{G}$ -invariant element y in A. Note that f is sum of an r-th symmetric power of  $x_0$  and some element of  $\operatorname{Sym}_r(V \cap \mathfrak{a})$ . Thus  $y \operatorname{mod} \mathfrak{a} = x^r$ . Hence  $x^r \in A^{\mathbf{G}}/A^{\mathbf{G}} \cap \mathfrak{a}$ .

**Remark 6.5.** Let **G** be an algebraic group **G** which acts on Spec *A* for some k-algebra *A* and let  $\mathfrak{a}$  be a **G**-stable ideal of *A*. Then the sequence

$$0 \longrightarrow \mathfrak{a}^{\mathbf{G}} \longrightarrow A^{\mathbf{G}} \longrightarrow (A/\mathfrak{a})^{\mathbf{G}}$$

is left exact and it induces a monomorphism  $A^{\mathbf{G}}/\mathfrak{a} \cap A^{\mathbf{G}} = A^{\mathbf{G}}/\mathfrak{a}^{\mathbf{G}} \hookrightarrow (A/\mathfrak{a})^{\mathbf{G}}$ . If  $\mathbf{G}$  is linearly reductive, then the sequence is exact and this monomorphism is an isomorphism. Theorem 6.4 states that if  $\mathbf{G}$  is geometrically reductive, then the monomorphism  $A^{\mathbf{G}}/\mathfrak{a} \cap A^{\mathbf{G}} \hookrightarrow (A/\mathfrak{a})^{\mathbf{G}}$  is integral.

Now we are going to formulate the main result of this section.

**Theorem 6.6.** Suppose that G is geometrically reductive. Let A be a finitely generated k-algebra such that Spec A admits an action of G. Then  $A^G$  is finitely generated k-algebra.

The theorem above was first proved by Nagata and here we follow Nagata's original proof. In the argument we denote the coaction of k[G] on A by  $d: A \to k[G] \otimes_k A$ . The proof relies on a series of partial results.

**Lemma 6.6.1.** Let  $A \hookrightarrow B$  be an integral morphism of k-algebras and suppose that B is finitely generated over k. Then A is finitely generated.

*Proof of the lemma.* Suppose that  $b_1,...,b_r$  are generators of B as a k-algebra. For every  $1 \le i \le r$  we have a polynomial relation

$$b_i^{n_i} + a_{i,n_i-1}b_i^{n_i-1} + \dots + a_{i,1}b_i + a_{i,0} = 0$$

where  $n_i > 0$  and  $a_{i,j} \in A$  for  $0 \le j \le n_i - 1$ . Suppose that  $\tilde{A}$  is a k-subalgebra of A generated by  $a_{i,j}$  for  $1 \le i \le r$  and  $0 \le j \le n_i - 1$ . Then B is finite over  $\tilde{A}$ . Since  $\tilde{A} \subseteq A \subseteq B$  and  $\tilde{A}$  is noetherian, we derive that A is finite over  $\tilde{A}$ . Hence A is finitely generated over k.

**Lemma 6.6.2.** Suppose that **G** is geometrically reductive. Let A be a k-algebra such that Spec A admits an action of **G**. Assume that A contains **G**-invariant zero divisor and that for every proper **G**-stable ideal  $\mathfrak{a}$  of A the k-algebra  $(A/\mathfrak{a})^G$  is finitely generated over k. Then  $A^G$  is finitely generated over k.

*Proof of the lemma.* Let f be a **G**-invariant zero divisor of A. By assumption both k-algebras  $(A/fA)^{\mathbf{G}}$  and  $(A/\operatorname{ann}(f))^{\mathbf{G}}$  are finitely generated over k. Now by combination of Lemma 6.6.1 and Theorem 6.4 we obtain that  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap fA$  and  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap \operatorname{ann}(f)$  are finitely generated over k. Let B be a finitely generated k-subalgebra of  $A^{\mathbf{G}}$  which maps surjectively onto  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap fA$  and  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap \operatorname{ann}(f)$ . Let  $u_1, ..., u_n$  be elements in A such that the image of  $B \cdot u_1 + ... + B \cdot u_n \subseteq A$  modulo  $\operatorname{ann}(f)$  contains a finite B-module  $(A/\operatorname{ann}(f))^{\mathbf{G}}$ . Fix  $a \in A^{\mathbf{G}}$ . Since B maps surjectively onto  $A^{\mathbf{G}}/A^{\mathbf{G}} \cap fA$ , there exist  $b \in B$  and  $c \in A$  such that a - b = fc. Note that  $fc \in A^{\mathbf{G}}$  and thus

$$(1 \otimes f) (d(c) - 1 \otimes c) = 0$$

This implies that c is send to  $(A/\operatorname{ann}(f))^{\mathbf{G}}$  modulo  $\operatorname{ann}(f)$ . Then  $c \in B \cdot u_1 + ... + B \cdot u_n$ . Hence  $a - b \in B \cdot f u_1 + ... + B \cdot f u_n$ . Therefore,  $a \in B[f u_1, ..., f u_n]$ . This completes the proof that  $A^{\mathbf{G}}$  is finitely generated over k.

**Lemma 6.6.3.** Suppose that **G** is geometrically reductive. Let  $A = \bigoplus_{n \in \mathbb{N}} A_n$  be a  $\mathbb{N}$ -graded k-algebra such that A admits an action of **G**. Assume that  $A_n$  is a **G**-subrepresentation of A for every  $n \in \mathbb{N}$  and that for every proper **G**-stable homogenous ideal a of A the k-algebra  $(A/a)^G$  is finitely generated over k. If A contains **G**-invariant zero divisor, then  $A^G$  is finitely generated over k.

*Proof of the lemma.* Let f be a **G**-invariant zero divisor of A. We may pick f such that it is homogenous. Then both ideals fA and ann(f) are homogenous, **G**-stable and proper in A. Now we proceed as in the proof of Lemma 6.6.2.

*Proof of the theorem.* We first prove the theorem in case of  $\mathbb{N}$ -graded k-algebras and then reduce the general case to this graded case.

Assume that  $A = \bigoplus_{n \in \mathbb{N}} A_n$  is  $\mathbb{N}$ -graded in such a way that  $A_0 = k$  and  $A_n$  is a  $\mathbb{G}$ -subrepresentation of A for every  $n \in \mathbb{N}$ . Since A is finitely generated over k and by virtue of noetherian induction, we assume that  $(A/\mathfrak{a})^G$  is finitely generated over k for every homogenous  $\mathbb{G}$ -stable proper ideal  $\mathfrak{a}$  of A. If there are  $\mathbb{G}$ -invariant zero divisors of A, then by Lemma 6.6.3 we deduce that  $A^G$  is finitely generated over k. So we may assume that  $A^G$  contains no zero divisors of A. Pick a nonzero homogenous element  $f \in A^G$  of positive degree. If there are no such elements, then  $A^G = A_0 = k$  and the result holds. So we may assume that such an element exists. Note that it is noninvertible. Consider  $x \in A$  such that  $fx \in A^G$ . Then

$$0 = d(fx) - 1 \otimes fx = d(f) \cdot d(x) - (1 \otimes f) \cdot (1 \otimes x) = (1 \otimes f) (d(x) - 1 \otimes x)$$

Since f is not a zero divisor in A, we derive that  $1 \otimes f$  is not a zero divisor in  $k[G] \otimes_k A$ . Thus  $d(x) = 1 \otimes x$  and  $x \in A^G$ . This shows that  $fA \cap A^G = fA^G$ . By Theorem 6.4  $(A/fA)^G$  is integral over  $A^G/fA \cap A^G = A^G/fA^G$ . Note that  $(A/fA)^G$  is finitely generated over k by inductive assumption. According to Lemma 6.6.1 we obtain that  $A^G/fA^G$  is finitely generated over k. Clearly

$$A^{\mathbf{G}} = \bigoplus_{n \in \mathbb{N}} A_n^{\mathbf{G}}$$

and hence  $A^{\mathbf{G}}/fA^{\mathbf{G}}$  inherits  $\mathbb{N}$ -grading from A. The ideal generated by elements of positive degree  $\left(A^{\mathbf{G}}/fA^{\mathbf{G}}\right)_{\perp}$  is finitely generated (as is every ideal in noetherian ring). Hence also

$$(A^{\mathbf{G}})_{+} = \bigoplus_{n \in \mathbb{N}_{+}} A_{n}^{\mathbf{G}}$$

is finitely generated (generating set consists of lifts of generators of  $(A^{\mathbf{G}}/fA^{\mathbf{G}})_{+}$  and f). This implies that  $A^{\mathbf{G}}$  is finitely generated over  $A_{0}^{\mathbf{G}} = k$ .

Now assume that *A* is an arbitrary finitely generated *k*-algebra. By noetherian induction we may assume that  $(A/\mathfrak{a})^{\mathbf{G}}$  is finitely generated over k for every proper **G**-stable ideal  $\mathfrak{a}$  of A. Pick a finitely dimensional G-subrepresentation V of A which contains some finite set of generators of A as a k-algebra. Define  $S = \operatorname{Sym}(V)$  and  $S_n = \operatorname{Sym}_n(V)$  for every  $n \in \mathbb{N}$ . Then S is  $\mathbb{N}$ -graded,  $S_0 = k$  and G acts on Spec S in such a way that  $S_n$  is a G-subrepresentation of S for every S. By the case considered above  $S^G$  is finitely generated over k. The canonical (induced by  $V \hookrightarrow A$ ) surjective morphism  $S \rightarrow A$  of k-algebras is also a morphism of representations of G. Let I be its kernel. Then *I* is a **G**-stable ideal of *S*. By Theorem 6.4 we derive that  $A^{\mathbf{G}} = (S/I)^{\mathbf{G}}$  is integral over its finitely generated k-subalgebra  $S^{\mathbf{G}}/I \cap S^{\mathbf{G}}$ . Moreover, by Lemma 6.6.2 we may assume that  $A^{\mathbf{G}}$ does not contain zero divisors of A. In particular, it is an integral domain. Hence  $S^{\mathbf{G}}/I \cap S^{\mathbf{G}}$  is a domain. Let B be the integral closure of  $S^{\mathbf{G}}/I \cap S^{\mathbf{G}}$  in the field L of fractions of  $A^{\mathbf{G}}$ . Since B is integral over  $A^{G}$ , Lemma 6.6.1 shows that it suffices to prove that B is finitely generated over k. This will follow, if we can show that *B* is a finite  $S^{\mathbf{G}}/I \cap S^{\mathbf{G}}$ -module. Since fields are Nagata rings, we may reduce this question to proving that L is a finite extension of the field K of fractions of  $S^{\mathbf{G}}/I \cap S^{\mathbf{G}}$ . Since  $K \subseteq L$  is algebraic (due to the fact that  $S^{\mathbf{G}}/I \cap S^{\mathbf{G}} \hookrightarrow A^{\mathbf{G}}$  is integral), it suffices to show that L is finitely generated field over K. For this pick a set S of nonzero divisors of A. Note that *S* is a multiplicative subset of *A*. Fix a maximal ideal  $\mathfrak{m} \subseteq S^{-1}A$ . Since nonzero elements of  $\mathfrak{m} \cap A^{\mathbf{G}}$  are zero divisors of A, we derive that  $\mathfrak{m} \cap A^{\mathbf{G}} = 0$ . Thus L is a subfield of  $S^{-1}A/\mathfrak{m}$ . The inclusion  $A \hookrightarrow S^{-1}A$  induces an isomorphism between the fraction field of  $A/\mathfrak{m} \cap A$  and the field  $S^{-1}A/\mathfrak{m}$ . By our assumption A is finitely generated over k. Thus the fraction field of  $A/\mathfrak{m} \cap A$  is finitely generated over  $\hat{k}$  as field. It follows that L is a field finitely generated over k. This implies that L is a field finitely generated over K. Therefore,  $A^{G}$  is finitely generated k-algebra.
