#### GEOMETRIC INVARIANT THEORY

## 1. Introduction

These notes present core results in geometric invariant theory. We mostly follow monography [Mumford et al., 1994]. We extensively use the language of schemes.

Throughout these notes we fix a field k and a group scheme G over k with the identity  $e : \operatorname{Spec} k \to G$  and the multiplication  $\mu : G \times_k G \to G$ .

### 2. Basic properties of quotients

We start by discussing some properties of submersive morphisms.

**Fact 2.1.** Submersive morphisms of schemes are local on target.

*Proof.* Fix a morphism  $q: X \to Y$  and suppose that there exists an open cover  $\mathcal{V}$  of Y such that for every  $V \in \mathcal{V}$  the restriction  $q^{-1}(V) \to V$  of q is submersive. Clearly q is surjective. Fix a subset U of Y such that  $q^{-1}(U)$  is open. A set  $q^{-1}(U \cap V) = q^{-1}(U) \cap q^{-1}(V)$  is an open subset of X for every  $V \in \mathcal{V}$ . Since the restriction  $q^{-1}(V) \to V$  is submersive for every  $V \in \mathcal{V}$ , we derive that  $U \cap V$  is open for every  $V \in \mathcal{V}$ . Thus

$$U = \bigcup_{V \in \mathcal{V}} U \cap V$$

is open in X. Therefore, q is submersive.

On the other hand if  $q: X \to Y$  is submersive, then for every open subscheme V the restriction  $q^{-1}(V) \to V$  is submersive.

**Fact 2.2.** Submersive and universally submersive morphisms descent along faithfuly flat and quasi-compact morphisms.

*Proof.* It suffices to prove that submersive morphisms have descent property. This follows from the fact that faithfully flat and quasi-compact morphism are submersive. Details are left for the reader.  $\Box$ 

In the remaining part of this section we fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ . The following result gives scheme-theoretic criterion for topological quotient in the case of group scheme actions.

**Proposition 2.3.** Let Y be a k-scheme with the trivial action of G and let  $q: X \to Y$  be a G-equivariant morphism. Assume that q is submersive and the morphism  $G \times_k X \to X \times_Y X$  induced by a and  $\operatorname{pr}_X$  is surjective. Then the diagram

$$\mathbf{G} \times_k X \xrightarrow{pr_X} X \xrightarrow{q} Y$$

is a cokernel in the category topological spaces.

*Proof.* Let  $\pi_1$  and  $\pi_2$  be distinct projections  $X \times_Y X \to X$ . Pick points  $x_1$  and  $x_2$  in X such that  $q(x_1) = q(x_2)$ . Then there exists a field extension K over k such that  $k(x_1) \subseteq K$  and  $k(x_2) \subseteq K$ .

These give rise to *K*-points  $\overline{x_1}$  and  $\overline{x_2}$  of *X* such that their images under *q* is the same *K*-point of *Y*. Since we have an identification

$$(X \times_Y X)(K) = X(K) \times_{Y(K)} X(K)$$

induced by  $\pi_1$  and  $\pi_2$ , we derive that there exists a K-point  $\overline{z}$  of  $X \times_Y X$  such that  $\pi_1(\overline{z}) = \overline{x_1}$  and  $\pi_2(\overline{z}) = \overline{x_2}$ . Let z be the point of  $X \times_Y X$  corresponding to  $\overline{z}$ . Then  $\pi_1(z) = x_1$  and  $\pi_2(z) = x_2$ . By assumption a and  $\operatorname{pr}_X$  induce surjection  $\mathbf{G} \times_k X \twoheadrightarrow X \times_Y X$ . Thus there exists a point u of  $\mathbf{G} \times_k X$  such that  $a(u) = x_1$  and  $\operatorname{pr}_X(u) = x_2$ . Thus  $x_1$  and  $x_2$  are identified by an equivalence relation on the underlying set of X which is determined by the pair  $(a,\operatorname{pr}_X)$ . Therefore, fibers of q are equivalence classes with respect to this relation. Since q is submersive, this implies that the diagram

$$\mathbf{G} \times_k X \xrightarrow{p_{\mathbf{r}_X}} X \xrightarrow{q} Y$$

is a cokernel in the category topological spaces.

**Definition 2.4.** Let *A* be a *k*-algebra and suppose that  $f : \operatorname{Spec} A \to X$  is an *A*-point of *X*. Then the morphism

$$\mathbf{G} \times_k \operatorname{Spec} K \xrightarrow{\langle a \cdot (1_{\mathbf{G}} \times_k f), \operatorname{pr}_2 \rangle} X \times_k \operatorname{Spec} K$$

is called *the orbit morphism of* f.

The following result is useful.

**Proposition 2.5.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Then the following assertions are equivalent.

- (i) Fix a point y in Y. Consider a geometric point  $\overline{x}$ : Spec  $K \to X$  such that  $q(\overline{x}) = \overline{y}$  is the geometric point with y as the underlying point. For every K with sufficiently large transcendence degree over k the orbit morphism  $o_{\overline{x}} : \mathbf{G} \times_k \operatorname{Spec} K \to X \times_k \operatorname{Spec} K$  induces a surjection  $\mathbf{G} \times_k \operatorname{Spec} K \to X_{\overline{y}}$ .
- (ii) The morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by  $(a, \operatorname{pr}_x) : \mathbf{G} \times_k X \to X \times_k X$  is surjective.

*Proof.* We start by proving the implication (i)  $\Rightarrow$  (ii). Assume that (i) holds. Consider a point z in  $X \times_Y X$ . Let y be a point of Y such that  $q(\operatorname{pr}_X(z)) = y = q(a(z))$ . Consider a geometric point  $\overline{x}$ : Spec  $K \to X$  such that  $q(\overline{x}) = \overline{y}$  is the geometric point with y as the underlying point. We may assume according to (i) that the orbit morphism  $o_{\overline{x}} : \mathbf{G} \times_k \operatorname{Spec} K \to X \times_k \operatorname{Spec} K$  induces a surjection  $\mathbf{G} \times_k \operatorname{Spec} K \to X_{\overline{y}}$ . Now suppose that L is an algebraically closed field containing K such that there exists an L-point  $\overline{z}$  of  $X \times_Y X$  with z as the underlying point and the map  $\mathbf{G}(L) \to X_{\overline{y}}(L)$  induced by  $o_{\overline{x}}$  on L-points is surjective. Then there exists an L-point g of  $\mathbf{G}$  such that  $g \cdot \operatorname{pr}_X(\overline{z}) = a(\overline{z})$ . Hence the map

$$G(L) \times X(L) \longrightarrow X(L) \times_{Y(L)} X(L)$$

induced by  $\langle a, \operatorname{pr}_{X} \rangle : \mathbf{G} \times_{k} X \to X \times_{k} X$  contains  $\overline{z}$  in its image. Indeed,  $(g, \operatorname{pr}_{X}(\overline{z}))$  is sent to  $\overline{z}$  under this map. Thus the set-theoretic image of the morphism  $\mathbf{G} \times_{k} X \to X \times_{Y} X$  contains z. This shows that **(ii)** holds.

Suppose now that (ii) holds. Pick a point *y* in *Y*. Let *K* be an algebraically closed field over *k* such that there is a surjective map

$$G(K) \times X(K) \longrightarrow X(K) \times_{Y(K)} X(K)$$

induced by  $\langle a, \operatorname{pr}_{x} \rangle : \mathbf{G} \times_{k} X \to X \times_{k} X$ . Assume also that K contains all residue fields of points in  $X_{y}$ . Pick a K-point  $\overline{x}$  in  $X_{y}$  and consider K-point  $\overline{y} = q(\overline{x})$ . Next fix any other K-point  $X_{y}$ . Since the map

$$\mathbf{G}(K) \times X(K) \longrightarrow X(K) \times_{Y(K)} X(K)$$

is surjective, we derive that there exists  $g \in \mathbf{G}(K)$  such that  $g \cdot \overline{x} = \overline{z}$ . This implies that the map  $\mathbf{G}(K) \to X_y(K)$  induced by the orbit map  $o_{\overline{x}}$  contains  $\overline{z}$  in its image. Since K contains all residue fields of points in  $X_y$ , the orbit morphism  $o_{\overline{x}}$  induces a surjection  $\mathbf{G} \times_k \operatorname{Spec} K \twoheadrightarrow X_y$  is surjective. Hence  $o_{\overline{x}}$  induces a surjection  $\mathbf{G} \times_k \operatorname{Spec} K \twoheadrightarrow X_{\overline{y}}$ .

Now we prove a series results concerning fpqc descent. For this we fix a k-scheme Y with the trivial action of G and a G-equivariant morphism  $q: X \to Y$ . Let  $g: Y' \to Y$  be a morphism of k-schemes and consider the cartesian square

$$X' \xrightarrow{g'} X$$

$$\downarrow^{q'} \qquad \downarrow^{q}$$

$$Y' \xrightarrow{g} Y$$

of k-schemes. Note that X' admits a unique action a' of G such that the square above consists of G-equivariant morphism (we consider g as a G-equivariant morphism between trivial G-schemes).

**Fact 2.6.** Suppose that g is faithfully flat and quasi-compact. Then the canonical morphism  $X' \times_{Y'} X' \to X \times_Y X$  is faithfully flat and quasi-compact and there is the cartesian square

$$\mathbf{G} \times_k X' \longrightarrow \mathbf{G} \times_k X$$

$$\downarrow \qquad \qquad \downarrow$$

$$X' \times_{Y'} X' \longrightarrow X \times_Y X$$

in which the left vertical arrow is induced by  $\langle a', \operatorname{pr}_{X'} \rangle : \mathbf{G} \times_k X' \to X' \times_k X'$ , the right vertical arrow is induced by  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \to X \times_k X$  and the bottom horizontal morphism is the canonical morphism.

Proof. Note that squares

are cartesian. Since both g and  $g' \times_k g'$  are faithfully flat and quasi-compact, we derive that both morphisms  $X' \times_{Y'} X' \to X' \times_Y X'$  and  $X' \times_Y X' \to X \times_Y X$  are faithfully flat and quasi-compact.

Then their composition i.e. the canonical morphism  $X' \times_{Y'} X' \to X \times_Y X$  is faithfully flat and quasi-compact.

**Fact 2.7.** Suppose that there exists an open cover V of Y such that for every V in V we have a surjection  $\mathbf{G} \times_k V \twoheadrightarrow q^{-1}(V) \times_V q^{-1}(V)$  induced by  $\operatorname{pr}_V$  and the restriction of the action to  $q^{-1}(V)$ . Then the morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by  $\operatorname{pr}_X$  and a is surjective.

Proof. It follows from the fact that

$$X \times_Y X = \bigcup_{V \in \mathcal{V}} q^{-1}(V) \times_V q^{-1}(V)$$

Finally we need the following notion

**Definition 2.8.** Let *Y* be a *k*-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Consider a pair

$$q_*\mathcal{O}_X \xrightarrow[q_*pr_*^{\#}]{q_*pr_*^{\#}} q_* (pr_X)_* \mathcal{O}_{\mathbf{G}\times_k X} = q_*a_*\mathcal{O}_{\mathbf{G}\times_k X}$$

of morphisms of sheaves of rings on Y. Suppose that  $q^{\#}: \mathcal{O}_{Y} \to q_{*}\mathcal{O}_{X}$  is a kernel of this pair. Then  $\mathcal{O}_{Y}$  is the sheaf of G-invariants for q.

**Proposition 2.9.** Suppose that g is faitfully flat and quasi-compact. Assume that q' is quasi-compact, semiseparated and  $\mathcal{O}_{Y'}$  is the sheaf of G-invariants for q'. Then  $\mathcal{O}_{Y}$  is the sheaf of G-invariants for q.

*Proof.* We denote by a' the action of G on X'. First note that q is semiseparated and quasi-compact morphism as these classes of morphisms admit descent along quasi-compact and faithfully flat morphisms. Since q is quasi-compact, semiseparated and g is flat, we derive that for every quasi-coherent sheaf  $\mathcal F$  on X the canonical morphism  $q'_*g'^*\mathcal F \to g^*q_*\mathcal F$  is an isomorphism. Thus the diagram

$$\mathcal{O}_{Y'} \xrightarrow{q^{\#}} q'_{*}\mathcal{O}_{X'} \xrightarrow{q'_{*}a^{r\#}} q'_{*} \left(\operatorname{pr}_{X'}\right)_{*} \mathcal{O}_{\mathbf{G} \times_{k} X'} = q'_{*}a'_{*} \mathcal{O}_{\mathbf{G} \times_{k} X'}$$

is isomorphic to the diagram

$$g^*\mathcal{O}_Y \xrightarrow{g^*q^\#} g^*\left(q_*\mathcal{O}_X\right) \xrightarrow[g^*q_*pr_v^*]{g^*q_*pr_v^\#}} g^*\left(q_*\left(\operatorname{pr}_X\right)_*\mathcal{O}_{\mathbf{G}\times_k X}\right) = g^*\left(q_*a_*\mathcal{O}_{\mathbf{G}\times_k X}\right)$$

Since  $\mathcal{O}_{Y'}$  is the sheaf of **G**-invariants for q', the first diagram is a kernel diagram. Hence the second is a kernel diagram. According to the fact that g is faithfully flat we deduce that the diagram

$$\mathcal{O}_{Y} \xrightarrow{q^{\#}} q_{*}\mathcal{O}_{X} \xrightarrow{q_{*}pr_{X}^{\#}} q_{*} \left(pr_{X}\right)_{*} \mathcal{O}_{\mathbf{G}\times_{k}X} = q_{*}a_{*}\mathcal{O}_{\mathbf{G}\times_{k}X}$$

is also a kernel diagram. Thus  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q.

**Proposition 2.10.** Suppose that there exists an open cover V of Y such that  $\mathcal{O}_V$  is the sheaf of G-invariants for the restriction  $q^{-1}(V) \to V$  of q for every V in V. Then  $\mathcal{O}_Y$  is the sheaf of G-invariants for q.

Proof of the lemma. The diagram

$$\mathcal{O}_{V} \xrightarrow{\left(q^{\#}\right)_{|V}} \left(q_{*}\mathcal{O}_{X}\right)_{|V} \xrightarrow{\left(q_{*}a^{\#}\right)_{|V}} \left(q_{*}\left(\operatorname{pr}_{X}\right)_{*} \mathcal{O}_{\mathbf{G}\times_{k}X}\right)_{|V} = \left(q_{*}a_{*}\mathcal{O}_{\mathbf{G}\times_{k}X}\right)_{|V}$$

is a kernel for every  $V \in \mathcal{V}$ . Since kernels are local, we derive that

$$\mathcal{O}_{Y} \xrightarrow{q^{\#}} q_{*}\mathcal{O}_{X} \xrightarrow{q_{*}a^{\#}} q_{*} \left(\operatorname{pr}_{X}\right)_{*} \mathcal{O}_{G\times_{k}X} = q_{*}a_{*}\mathcal{O}_{G\times_{k}X}$$

is a kernel of a pair  $(q_*a^\#, q_*pr_X^\#)$ . Thus  $\mathcal{O}_Y$  is the sheaf of **G**-invariant for q.

### 3. CATEGORICAL AND GEOMETRIC QUOTIENTS

In this section we fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ .

**Definition 3.1.** Let Y be a k-scheme with the trivial action of G and let  $q: X \to Y$  be a G-equivariant morphism. Suppose that the following conditions hold.

- **(1)** *q* is submersive.
- (2) The morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by  $\langle a, \operatorname{pr}_x \rangle : \mathbf{G} \times_k X \to X \times_k X$  is surjective.
- (3)  $\mathcal{O}_Y$  is the sheaf of **G**-invariant for q.

Then *q* is a geometric quotient of *X*.

**Corollary 3.2.** *Let q be a geometric quotient of X. Then the diagram* 

$$\mathbf{G} \times_k X \xrightarrow{pr_X} X \xrightarrow{q} Y$$

is a cokernel in the category of ringed spaces.

*Proof.* Due to the fact that  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q it suffices to prove that

$$\mathbf{G} \times_k X \xrightarrow{pr_{\mathbf{Y}}} X \xrightarrow{q} Y$$

is the cokernel in the category of topological spaces. This follows from Proposition 2.3.

**Corollary 3.3.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Then the following assertions are equivalent.

- (i) There exists an open affine cover V of Y such that for every V in V the restriction  $q^{-1}(V) \to V$  of q is a geometric quotient.
- (ii) There exists an open cover V of Y such that for every V in V the restriction  $q^{-1}(V) \to V$  of q is a geometric quotient.
- (iii) q is a geometric quotient.

*Proof.* This is a consequence of Facts 2.1, 2.7 and Proposition 2.10.

**Definition 3.4.** Let  $q: X \to Y$  be a morphism of k-schemes such that the diagram

$$\mathbf{G} \times_k X \xrightarrow{g} X \xrightarrow{q} Y$$

is a cokernel in the category of k-schemes. Then  $q: X \to Y$  is a categorical quotient of X.

**Fact 3.5.** Every geometric quotient is categorical.

*Proof.* Categorical quotient is a cokernel in the category of k-schemes. On the other hand geometric quotient is a cokernel in the category of locally ringed spaces and hence it also satisfies cokernel property in its full subcategory of k-schemes. Thus every geometric quotient is categorical.

Let  $q: X \to Y$  be a morphism of k-schemes such that  $q \cdot \operatorname{pr}_X = q \cdot a$ . For a morphism  $g: Y' \to Y$  of k-schemes consider the cartesian square

$$X' \xrightarrow{g'} X$$

$$q' \downarrow \qquad \qquad \downarrow q$$

$$Y' \xrightarrow{g} Y$$

Then there exists a unique action  $a' : \mathbf{G} \times_k X' \to X'$  of  $\mathbf{G}$  on X' such that the square above consists of  $\mathbf{G}$ -equivariant morphism (we consider Y, Y' as  $\mathbf{G}$ -schemes equipped with trivial  $\mathbf{G}$ -actions). Keeping this in mind we have the following.

**Corollary 3.6.** Let  $g: Y' \to Y$  be a faithfully flat and quasi-compact morphism. Suppose that q' is a geometric quotient and a semiseparated morphism, then q is a geometric quotient.

*Proof.* This follows from Facts 2.2, 2.6 and Proposition 2.9.

**Definition 3.7.** A morphism  $q: X \to Y$  is a uniform categorical (geometric) quotient of X if for every flat morphism  $g: Y' \to Y$  of k-schemes a base change  $q': X' \to Y'$  of q along g is a categorical (geometric) quotient of X'.

**Definition 3.8.** A morphism  $q: X \to Y$  is a universal categorical (geometric) quotient of X if for every morphism  $g: Y' \to Y$  of k-schemes a base change  $q': X' \to Y'$  of q along g is a categorical (geometric) quotient of X'.

Now we show that uniform and universal categorical quotients are local on the target.

**Theorem 3.9.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Then the following assertions are equivalent.

- (i) There exists an open cover V of Y such that for every V in V morphism  $q^{-1}(V) \to V$  is a universal (uniform) categorical quotient.
- (ii) q is a universal (uniform) categorical quotient.
- (iii) For every affine k-scheme Y' and a (flat) morphism  $g: Y' \to Y$  of k-schemes a base change  $q': X' \to Y'$  of q along g is a categorical quotient.
- (iv) There exists an open affine cover V of Y such that for every V in V morphism  $q^{-1}(V) \to V$  is a universal (uniform) categorical quotient.

For the proof we need the following.

**Lemma 3.9.1.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. If there exists an open cover V of Y such that for every V in V morphism  $q^{-1}(V) \to V$  is a uniform categorical quotient, then q is a categorical quotient.

*Proof of the lemma.* We first prove categorical case. For every open subscheme W of Y we denote by  $q_W$  the restriction  $q^{-1}(W) \to W$ . For this pick a **G**-equivariant morphism  $g: X \to Z$  into a scheme with the trivial **G**-action. Since the restriction  $q_V$  is a categorical quotient for every  $V \in \mathcal{V}$ , there exists a unique morphism  $f_V: V \to Z$  such that

$$g_{|q^{-1}(V)} = f_V \cdot q_V$$

Suppose that  $V_1, V_2 \in \mathcal{V}$ . Then

$$g_{|q^{-1}(V_1\cap V_2)}=\left(f_{V_1}\right)_{|V_1\cap V_2}\cdot q_{V_1\cap V_2}$$

and

$$g_{|q^{-1}(V_1\cap V_2)}=\left(f_{V_2}\right)_{|V_1\cap V_2}\cdot q_{V_1\cap V_2}$$

Since  $q_{V_1}$  and  $q_{V_2}$  are uniform categorical quotients, we derive that  $q_{V_1 \cap V_2}$  is also categorical quotient. Thus equalities above show that  $(f_{V_1})_{|V_1 \cap V_2} = (f_{V_2})_{|V_1 \cap V_2}$ . Hence  $\{f_V\}_{V \in \mathcal{V}}$  glue to a morphism  $f: Y \to Z$  such that  $g = f \cdot q$ . The uniqueness of f follows from uniqueness of  $\{f_V\}_{V \in \mathcal{V}}$ . Thus q is a categorical quotient.  $\square$ 

*Proof of the theorem.* Implications (ii)  $\Rightarrow$  (iii) and (iv)  $\Rightarrow$  (v) are obvious.

We prove (i)  $\Rightarrow$  (ii). Suppose that (i) holds. Pick a (flat) morphism  $g: Y' \to Y$  and fix a cartesian square

$$X' \xrightarrow{g'} X$$

$$\downarrow^{q'} \qquad \downarrow^{q} \qquad \downarrow^{q} \qquad \qquad Y' \xrightarrow{\sigma} Y$$

Then  $\mathcal{V}' = \{g^{-1}(V) | V \in \mathcal{V}\}$  is an open cover of Y' such that for every  $V \in \mathcal{V}'$  the morphism  $q'^{-1}(V) \to V$  is a uniform categorical quotient. By Lemma 3.9.1 we derive that q' is a categorical quotient. This is (ii).

Assume that (iii) holds. Pick an open affine subset V of Y. Consider a (flat) morphism  $g:V'\to V$  and pick a cartesian square

$$U' \xrightarrow{g'} q^{-1}(V)$$

$$\downarrow^{q_V} \downarrow \qquad \downarrow^{q_V}$$

$$V' \xrightarrow{g} V$$

where  $q_V: q^{-1}(V) \to V$  is the restriction of q. Then for every open affine subset W of V' the restriction  $q_{V'}^{-1}(W) \to W$  of  $q_{V'}$  is a universal (uniform) categorical quotient according to (iii) (and the fact that  $W \hookrightarrow V'$  composed with g is flat). By Lemma 3.9.1 it follows that  $q_{V'}$  is a categorical quotient. Thus  $q_V$  is a universal (uniform) categorical quotient. This holds for every open affine subset V of Y. This is (iv) and hence (iii)  $\Rightarrow$  (iv) holds.

Similar result holds for uniform and universal geometric quotients.

**Theorem 3.10.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Then the following assertions are equivalent.

- (i) There exists an open cover V of Y such that for every V in V morphism  $q^{-1}(V) \to V$  is a universal (uniform) geometric quotient.
- (ii) q is a universal (uniform) geometric quotient.
- (iii) For every affine k-scheme Y' and a (flat) morphism  $g: Y' \to Y$  of k-schemes a base change  $q': X' \to Y'$  of q along g is a geometric quotient.
- (iv) There exists an open affine cover V of Y such that for every V in V morphism  $q^{-1}(V) \to V$  is a universal (uniform) geometric quotient.

*Proof.* The implication (i)  $\Rightarrow$  (ii) follows from Corollary 3.3. Implication (ii)  $\Rightarrow$  (iii) and (iv)  $\Rightarrow$  (i) are obvious. It suffices to prove that (iii)  $\Rightarrow$  (iv). Assume that (iii) holds. Pick an open affine subset V of Y. Consider a (flat) morphism  $g: V' \to V$  and pick a cartesian square

$$U' \xrightarrow{g'} q^{-1}(V)$$

$$\downarrow^{q_V} \downarrow \qquad \downarrow^{q_V} \qquad \downarrow$$

where  $q_V: q^{-1}(V) \to V$  is the restriction of q. Then for every open affine subset W of V' the restriction  $q_{V'}^{-1}(W) \to W$  of  $q_{V'}$  is a universal (uniform) geometric quotient according to (iii) (and the fact that  $W \to V'$  composed with g is flat). By Corollary 3.3 it follows that  $q_{V'}$  is a geometric quotient. Thus  $q_V$  is a universal (uniform) geometric quotient. This holds for every open affine subset V of Y. This implies (iv) and hence (iii)  $\Rightarrow$  (iv) holds.

Now we give a simple example of a universal geometric quotient.

**Proposition 3.11.** Suppose that **G** is a quasi-compact group scheme over k. Let Y be a k-scheme and consider  $\mathbf{G} \times_k Y$  with the action of **G** induced by the regular action on the left factor. Then  $\operatorname{pr}_Y : \mathbf{G} \times_k Y \to Y$  is a universal geometric quotient.

*Proof.* Clearly  $\operatorname{pr}_Y$  is univerally submersive (it is even universally open). Let  $\mu: \mathbf{G} \times_k \mathbf{G} \to \mathbf{G}$  be the multiplication morphism and let  $\operatorname{pr}_{23}: \mathbf{G} \times_k \mathbf{G} \times Y \to \mathbf{G} \times_k Y$  be the projection on the last two factors. Then the morphism

$$\mathbf{G} \times_k \mathbf{G} \times_k Y \to (\mathbf{G} \times_k Y) \times_Y (\mathbf{G} \times_k Y) = \mathbf{G} \times_k \mathbf{G} \times_k Y$$

induced by  $(\mu \times_k 1_Y, \operatorname{pr}_{23}) : \mathbf{G} \times_k \mathbf{G} \times_k Y \to (\mathbf{G} \times_k Y) \times_k (\mathbf{G} \times_k Y)$  is an isomorphism. We show that  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for  $\operatorname{pr}_Y$ . For this pick an affine open subset V of Y. It suffices to check that the diagram

$$\Gamma(V, \mathcal{O}_Y) \xrightarrow{\operatorname{pr}_Y^{\#}} \Gamma\left(\mathbf{G} \times_k V, \mathcal{O}_{\mathbf{G} \times_k Y}\right) \xrightarrow{\left(\mu \times_k 1_Y\right)^{\#}} \Gamma\left(\mathbf{G} \times_k \mathbf{G} \times_k V, \mathcal{O}_{\mathbf{G} \times_k \mathbf{G} \times_k Y}\right)$$

is a kernel. Since G is quasi-compact and separated (every group k-scheme is separated), we derive that the diagram above is isomorphic with

$$\Gamma(V, \mathcal{O}_{Y}) \xrightarrow{f \mapsto 1 \otimes f} \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) \otimes_{k} \Gamma(V, \mathcal{O}_{Y}) \xrightarrow{\chi \otimes f \mapsto \mu^{\#}(\chi) \otimes f} \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) \otimes_{k} \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) \otimes_{k} \Gamma(V, \mathcal{O}_{Y})$$

Thus the first diagram is the kernel diagram if  $f \mapsto 1 \otimes f$  induces an isomorphism of  $\Gamma(V, \mathcal{O}_Y)$  with subspace of  $\Gamma(G, \mathcal{O}_G) \otimes_k \Gamma(V, \mathcal{O}_Y)$  given by formula

$$\{\chi \in \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) | \mu^{\#}(\chi) = 1 \otimes \chi\} \otimes_{k} \Gamma(V, \mathcal{O}_{Y})$$

Hence it suffices to prove that

$$\{\chi \in \Gamma(\mathbf{G}, \mathcal{O}_{\mathbf{G}}) | \mu^{\#}(\chi) = 1 \otimes \chi\} = \text{constant functions on } \mathbf{G}$$

For this pick a k-algebra A and let  $g: \operatorname{Spec} A \to \mathbf{G}$  be an A-point. Next let  $e: \operatorname{Spec} A \to \mathbf{G}$  be an A-point of  $\mathbf{G}$  which corresponds to the identity element of  $\mathbf{G}$ . Suppose that a regular function  $\chi$  in  $\mathbf{G}$  satisfies  $\mu^{\#}(\chi) = 1 \otimes \chi$ . Then

$$g^{\#}(\chi) = \langle g, e \rangle^{\#} \mu^{\#}(\chi) = \langle g, e \rangle^{\#} (1 \otimes \chi) = e^{\#}(\chi)$$

Recall that e is given by the composition of the structural morphism  $\operatorname{Spec} A \to \operatorname{Spec} k$  and the k-point  $\operatorname{Spec} k \to \mathbf{G}$  determined by the identity of  $\mathbf{G}$ . Thus  $g^{\#}(\chi)$  is an element of k. Since this follows for every  $g:\operatorname{Spec} A \to \mathbf{G}$ , we derive that  $\chi$  is a constant function. This completes the proof of our claim that

$$\Gamma(V, \mathcal{O}_{Y}) \xrightarrow{\operatorname{pr}_{Y}^{\#}} \Gamma\left(\mathbf{G} \times_{k} V, \mathcal{O}_{\mathbf{G} \times_{k} Y}\right) \xrightarrow{\left(\mu \times_{k} 1_{Y}\right)^{\#}} \Gamma\left(\mathbf{G} \times_{k} \mathbf{G} \times_{k} V, \mathcal{O}_{\mathbf{G} \times_{k} \mathbf{G} \times_{k} Y}\right)$$

is the kernel diagram and hence  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for  $\operatorname{pr}_Y$ . Therefore, we proved that  $\operatorname{pr}_Y$  is a geometric quotient of  $\mathbf{G} \times_k Y$ . Consider any morphism  $Y' \to Y$ . Then base change of  $\operatorname{pr}_Y$  along this morphism is  $\operatorname{pr}_{Y'}$ . We conclude that  $\operatorname{pr}_Y$  is a universal geometric quotient for  $\mathbf{G} \times_k Y$ .

#### 4. CLOSED AND SEPARATED ACTIONS

In this section we fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ .

**Definition 4.1.** The action of **G** on *X* is *closed* if for every algebraically closed field *K* and a *K*-point  $\overline{x}$  of  $X \times_k \operatorname{Spec} K$  the orbit morphism  $\mathbf{G} \times_k \operatorname{Spec} K \to X \times_k \operatorname{Spec} K$  of  $\overline{x}$  has closed image.

**Definition 4.2.** The action of **G** on *X* is *separated* if the morphism  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \to X \times_k X$  has closed set-theoretic image.

**Theorem 4.3.** Let  $q: X \to Y$  be a geometric quotient of X. Assume that q is universally submersive. Then the following assertions are equivalent.

- (i) The action of G on X is separated.
- (ii) Y is separated.

*Proof.* We have a cartesian square

$$X \times_{Y} X \xrightarrow{} X \times_{k} X$$

$$\downarrow \qquad \qquad \downarrow q \times_{k} q$$

$$Y \xrightarrow{\Delta_{Y}} Y \times_{k} Y$$

It follows that  $X \times_Y X \hookrightarrow X \times_k X$  is a locally closed immersion. Since q is a geometric quotient, we derive that  $\langle a, \operatorname{pr}_X \rangle$  factors as a surjective morphism  $\mathbf{G} \times_k X \twoheadrightarrow X \times_Y X$  followed by the immersion  $X \times_Y X \hookrightarrow X \times_k X$ . Thus the action of  $\mathbf{G}$  on X is separated if and only if  $X \times_Y X$  is a closed subscheme of  $X \times_k X$ . Since q is universally submersive, we derive that  $q \times_k q$  is submersive. As the square above is cartesian we derive that  $\Delta_Y(Y) \subseteq Y \times_k Y$  is closed if and only if  $X \times_Y X \subseteq X \times_k X$  is closed. Therefore, Y is separated if and only if the action of  $\mathbf{G}$  on X is separated.

### 5. GEOMETRIC QUOTIENTS OF FREE ACTIONS AND PRINCIPAL BUNDLES

In this section we fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ .

**Definition 5.1.** The action of **G** on *X* is *free* if the morphism  $\langle a, \operatorname{pr}_X \rangle : \mathbf{G} \times_k X \to X \times_k X$  is a closed immersion.

**Definition 5.2.** Let x be a k-point of X. We consider x as a morphism  $\operatorname{Spec} k \to X$ . Suppose that the orbit morphism  $\mathbf{G} \to X$  of x is a closed immersion. Then the action of  $\mathbf{G}$  on X has a closed free orbit at x.

**Fact 5.3.** *If the action of* G *on* X *is free, then every k-point of* X *has a closed free orbit.* 

The following result states that over special type of local complete noetherian *k*-algebras geometric quotients of free actions correspond to trivial **G**-bundles.

**Theorem 5.4.** Suppose that k is an algebraically closed field and G is a smooth algebraic group over k. Let  $q: X \to Y$  be a geometric quotient and a morphism locally of finite type and let Y be the spectrum of a complete local noetherian k-algebra such that the residue field of the closed point of Y is k. Then the following assertions hold.

(1) If x is a k-point of X which has a closed free orbit, then there exists a G-equivariant, étale and surjective morphism  $f: G \times_k Y \to X$  such that the triangle

$$\mathbf{G} \times_k Y \xrightarrow{f} X$$

$$\operatorname{pr}_Y \qquad \qquad q$$

is commutative and the morphism

$$Y = \operatorname{Spec} k \times_k Y \xrightarrow{e \times_k 1_Y} \mathbf{G} \times_k Y \xrightarrow{f} X$$

is a section of q.

**(2)** If the action of G on X is free, then f is an isomorphism.

The proof relies on two algebraic lemmas. The first describe free actions in context of complete rings (it is [Mumford et al., 1994, lemma on page 18]) and the second is a version of Hensel's lemma.

**Lemma 5.4.1.** Let  $(R, \mathfrak{m}, k)$  be a complete local noetherian k-algebra and let  $\sigma : R \to R[[x_1, ..., x_n]]$  be a local morphism into a ring of formal power series over R. Assume that the composition

$$R \xrightarrow{\sigma} R[[x_1, ..., x_n]] \xrightarrow{f \mapsto f \bmod (x_1, ..., x_n)} R$$

is the identity and the composition

$$R \xrightarrow{\sigma} R[[x_1, ..., x_n]] \xrightarrow{f \mapsto f \bmod \mathfrak{m}} (R/\mathfrak{m})[[x_1, ..., x_n]] = k[[x_1, ..., x_n]]$$

is surjective. Consider elements  $y_1,...,y_n$  of R such that  $\sigma(y_i) \mod \mathfrak{m} = x_i$  for i=1,...,n. Then the composition

$$R \xrightarrow{\sigma} R[[x_1, ..., x_n]] \xrightarrow{f \mapsto f \bmod (y_1, ..., y_n)} (R/(y_1, ..., y_n))[[x_1, ..., x_n]]$$

is an isomorphism.

*Proof of the lemma.* For convienience let  $\phi$  denote the morphism given by the rule  $r \mapsto \sigma(r) \mod (y_1, ..., y_n)$ . Also denote  $R/(y_1, ..., y_n)$  by S. According to assumptions we have

$$\sigma(y_i) = x_i + y_i + \sum_{i=1}^{n} x_j \cdot \mathfrak{m}[[x_1, ..., x_n]]$$

for each i. Thus  $\phi(y_i) = \sum_{j=1}^n f_{ij} \cdot x_j$  where  $f_{ij} \in S$  are elements such that the matrix  $[f_{ij}]_{1 \le i,j \le n}$  is invertible in S. Hence

$$S[[x_1,...,x_n]] = S[[\phi(y_1),...,\phi(y_n)]]$$

and  $\phi$  composed with  $S[[\phi(y_1),...,\phi(y_n)]] \twoheadrightarrow S$  is the quotient morphism  $R \twoheadrightarrow S$ . From this observations we derive that  $\phi$  is surjective. It remains to prove that it is injective. Consider z in R such that  $\phi(z) = 0$ . Suppose that  $z \in (y_1,...,y_n)^m$  for some  $m \in \mathbb{N}$ . Write

$$z = \sum_{\alpha \in \Lambda} c_{\alpha} \cdot y_1^{\alpha_1} ... y_n^{\alpha_n}$$

for some  $c_{\alpha} \in R$  where  $\Lambda = \{\alpha \in \mathbb{N}^n \mid \alpha_1 + ... + \alpha_n = m\}$ . Hence

$$0 = \phi(z) = \sum_{\alpha \in \Lambda} \phi(c_{\alpha}) \cdot \phi(y_1)^{\alpha_1} ... \phi(y_n)^{\alpha_n}$$

Thus  $\phi(c_{\alpha}) \in (\phi(y_1),...,\phi(y_n))$  for every  $\alpha \in \Lambda$ . Since  $\phi$  composed with  $S[[\phi(y_1),...,\phi(y_n)]] \twoheadrightarrow S$  is the quotient morphism  $R \twoheadrightarrow S$ , we derive that

$$c_{\alpha} \mod (y_1, ..., y_n) = \phi(c_{\alpha}) \mod (\phi(y_1), ..., \phi(y_n)) = 0$$

for every  $\alpha \in \Lambda$ . Thus  $c_{\alpha} \in (y_1, ..., y_n)$  for every  $\alpha \in \Lambda$ , which implies that  $z \in (y_1, ..., y_n)^{m+1}$ . Thus we proved that

$$\phi(z) = 0 \text{ and } z \in (y_1, ..., y_n)^m \Rightarrow z \in (y_1, ..., y_n)^{m+1}$$

By m-adic completeness of R this implies that  $\phi(z)=0$  if and only if z=0. Hence  $\phi$  is also injective.

**Lemma 5.4.2.** Let  $(R, \mathfrak{m})$  be a complete local noetherian ring and let  $R \to S$  be a local morphism into a local noetherian ring. Suppose that there exists a finitely generated R-submodule R of R such that

$$S = N + \mathfrak{m}S$$

Then S = N.

*Proof of the lemma.* Pick s in S. Since  $S = N + \mathfrak{m}S$ , there exists a sequence  $\{x_n\}_{n \in \mathbb{N}}$  such that  $x_n \in \mathfrak{m}^n N$  and

$$s - \sum_{i < n} x_i \in \mathfrak{m}^{n+1} S$$

According to the assumption that  $(R, \mathfrak{m})$  is complete with respect to  $\mathfrak{m}$ -adic topology and N is finitely generated over R, we deduce that N is complete with respect to  $\mathfrak{m}$ -adic topology. Hence there exists a unique element x in N such that

$$x = \sum_{n \in \mathbb{N}} x_n$$

where above series is convergent with respect to m-adic topology. Note also that

$$x - \sum_{i < n} x_i \in \mathfrak{m}^{n+1} N$$

for every  $n \in \mathbb{N}$ . Thus we have

$$s - x = \left(s - \sum_{i \le n} x_i\right) - \left(x - \sum_{i \le n} x_i\right) \in \mathfrak{m}^{n+1}S + \mathfrak{m}^{n+1}N = \mathfrak{m}^{n+1}S$$

for every  $n \in \mathbb{N}$ . Hence

$$x - s \in \bigcap_{n \in \mathbb{N}} \mathfrak{m}^n S$$

Since  $R \to S$  is local morphism and S is a local ring, we deduce that  $\mathfrak{m}S$  is contained in the maximal ideal of S. By assumptions S is noetherian. Therefore, S is separated with respect to  $\mathfrak{m}$ -adic topology. This implies that

$$0 = \bigcap_{n \in \mathbb{N}} \mathfrak{m}^n S$$

Thus s - x = 0 and we infer that s is an element of N. This completes the proof that S = N.

In what follows we shall denote by Gx the closed subscheme determined by the orbit morphism  $G \to X$  of a k-point x of X which has a closed free orbit. For readers convienience we include the following lemmas, which have topological content.

**Lemma 5.4.3.** Let  $q: X \to Y$  be a geometric quotient and assume that Y is the spectrum of a local k-algebra such that the residue field of the closed point o of Y is k. Let x be a k-point of X with free closed orbit, then  $q^{-1}(o) = \mathbf{G}x$  as closed subschemes of X.

*Proof of the lemma.* Morphism q induces the morphism of residue fields  $k(q(x)) \hookrightarrow k(x) = k$  over k. This implies that k(q(x)) = k and hence q(x) is a k-point of Y. Note that o is the unique k-point of Y. Thus q(x) = o. Clearly  $q^{-1}(o)$  is a closed G-stable subscheme of X (it is the preimage of o under G-equivariant q), that contains x. Since G is the smallest closed G-stable subscheme of X containing x, we deduce that G  $x \in q^{-1}(o)$  scheme-theoretically. Consider the pair of arrows

$$\mathbf{G} \times_k X \xrightarrow{pr_X} X$$

Passing to functors of points we obtain that  $a^{-1}(\mathbf{G}x) = \operatorname{pr}_X(\mathbf{G}.x)$ . Since q is the cokernel of the pair  $(a,\operatorname{pr}_X)$  in the category of topological spaces, we deduce that there exists a closed subset Z of Y such that  $q^{-1}(Z) = \mathbf{G}x$ . Clearly  $o \in Z$  and hence  $q^{-1}(o) \subseteq \mathbf{G}x$  set-theoretically. On the other hand above we proved that  $\mathbf{G}x \subseteq q^{-1}(o)$  scheme-theoretically. This can only happen if  $q^{-1}(o) = \mathbf{G}x$  as closed subschemes of X.

**Lemma 5.4.4.** Let  $q: X \to Y$  be a geometric quotient and assume that Y is the spectrum of a local kalgebra such that the residue field of the closed point o of Y is k. Let U be an open **G**-stable subset of X which contain a k-point. Then U = X.

Proof of the lemma. Consider the pair of arrows

$$\mathbf{G} \times_k X \xrightarrow{pr_{\mathbf{v}}} X$$

Since U is **G**-stable open subset of X, we derive that  $\operatorname{pr}_X^{-1}(U) = a^{-1}(U)$ . Next by definition q is the cokernel of the above pair in the category of topological spaces. Hence there exists an open subset V of Y such that  $U = q^{-1}(V)$ . Since U contains a k-point of X, we deduce as in Lemma 5.4.3 that  $o \in V$ . Thus V = Y and finally  $U = q^{-1}(V) = X$ .

*Proof of the theorem.* We first prove **(1)**. Denote by o the closed point of Y. Assume that x is a k-point of X which has a closed free orbit. Consider the surjective morphism  $\mathcal{O}_{X,x} \twoheadrightarrow \mathcal{O}_{G,e}$  induced by the orbit morphism  $G \hookrightarrow X$  of x. Since G is smooth over k, the ring  $\mathcal{O}_{G,e}$  is regular. Pick a system of parameters  $x_1,...,x_n$  of  $\mathcal{O}_{G,e}$  and let  $y_1,...,y_n$  be elements of  $\mathcal{O}_{X,x}$  such that  $y_i$  is send to  $x_i$  by the morphism  $\mathcal{O}_{X,x} \twoheadrightarrow \mathcal{O}_{G,e}$  for  $1 \le i \le n$ . Define S to be the quotient ring  $\mathcal{O}_{X,x}/(y_1,...,y_n)$ . The morphism q induces the morphism  $q^\#: \mathcal{O}_{Y,o} \to \mathcal{O}_{X,x}$  and hence the morphism  $\mathcal{O}_{Y,o} \to S$ . By Lemma 5.4.3 we have

$$S/\mathfrak{m}_o S = k$$

where  $\mathfrak{m}_o$  is the maximal ideal of  $\mathcal{O}_{Y,o}$ . According to Lemma 5.4.2 we derive that  $\mathcal{O}_{Y,o} \to S$  is surjective. Let  $f: \mathbf{G} \times_k \operatorname{Spec} S \to X$  be the unique  $\mathbf{G}$ -equivariant morphism induced by the surjection  $\mathcal{O}_{X,x} \twoheadrightarrow S$ . We have a commutative square

$$G \times_k \operatorname{Spec} S \xrightarrow{f} X$$

$$\operatorname{pr}_{\operatorname{Spec} S} \downarrow \qquad \qquad \downarrow q$$

$$\operatorname{Spec} S \xrightarrow{f} Y$$

where j is a closed immersion induced by  $\mathcal{O}_{Y,o} \twoheadrightarrow S$ . According to assumptions q is locally of finite type. Moreover, G is an algebraic group over k and hence  $\operatorname{pr}_{\operatorname{Spec} S}$  is locally of finite type. These two assertions together with the fact that  $\operatorname{Spec} S \hookrightarrow Y$  is a closed immersion of noetherian schemes (and thus is of finite type) imply that f is locally of finite type. Then by Lemma 5.4.1 we deduce that f induces an isomorphism

$$\widehat{\mathcal{O}_{X,x}} \longrightarrow \hat{S}[[x_1,...,x_n]] = \hat{S} \hat{\otimes}_k \widehat{\mathcal{O}_{G,e}}$$

of complete local rings. Since f is locally of finite type, it follows that f is étale at a k-point of  $\mathbf{G} \times_k \operatorname{Spec} S$  determined by the unique k-point of  $\operatorname{Spec} S$  and  $e \in \mathbf{G}$ . Let U be an étale locus of f. It contains a k-point and hence it is nonempty. Moreover, U is open (it is étale locus) subset of X. Since f is  $\mathbf{G}$ -equivariant, we derive that U is  $\mathbf{G}$ -stable. Similarly f(U) is open  $\mathbf{G}$ -stable subset of X and  $X \in f(U)$ . Thus by Lemma 5.4.4 we deduce that

$$U = \mathbf{G} \times_k \operatorname{Spec} S, f(U) = X$$

Therefore, f is étale and surjective. Now we pullback  $q: X \to Y$  along the closed immersion  $\operatorname{Spec} S \hookrightarrow Y$ . We obtain a cartesian square

$$\tilde{X} \stackrel{\tilde{j}}{\longleftarrow} X \\
\downarrow^{\tilde{q}} \qquad \qquad \downarrow^{q} \\
\text{Spec } S \stackrel{\tilde{j}}{\longleftarrow} Y$$

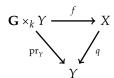

Then f factors as a morphism  $\mathbf{G} \times_k \operatorname{Spec} S \to \tilde{X}$  followed by a closed immersion  $\tilde{f}$ . Since f is étale and surjective, we deduce that  $\tilde{f}$  is étale and surjective. This implies that  $\tilde{f}$  is an isomorphism of schemes. By definition of geometric quotient we derive that the diagram

$$\mathcal{O}_{Y} \xrightarrow{q^{\#}} q_{*}\mathcal{O}_{X} \xrightarrow{q_{*}a^{\#}} q_{*} \left(\operatorname{pr}_{X}\right)_{*} \mathcal{O}_{\mathbf{G} \times_{k} X} = q_{*}a_{*}\mathcal{O}_{\mathbf{G} \times_{k} X}$$

is the kernel in the category of sheaves on Y. Hence  $q^{\#}: \mathcal{O}_{Y} \to q_{*}\mathcal{O}_{X}$  is a monomorphism of sheaves. On the other hand we have

$$q^{\#} = j_{*}q_{*} (\tilde{j}^{-1})^{\#} \cdot j_{*}\tilde{q}^{\#} \cdot j^{\#}$$

and thus  $j^{\#}$  is a monomorphism. Since j is a closed immersion, we infer that j is an isomorphism. Therefore, we can identify Spec S with Y. Then f is a morphism which makes the triangle

commutative. This completes the proof of (1).

For the proof of (2) consider the section  $s: Y \to X$  described in (1). Then f fits into a cartesian square

$$\mathbf{G} \times_{k} Y \xrightarrow{f} X \times_{Y} Y = X$$

$$\downarrow_{1_{G} \times_{Y} s} \qquad \downarrow_{1_{X} \times_{Y} s}$$

$$\mathbf{G} \times_{k} X \xrightarrow{\phi} X \times_{Y} X$$

where  $\phi$  is a closed immersion induced by the closed immersion  $(a, \operatorname{pr}_X) : \mathbf{G} \times_k X \hookrightarrow X \times_k X$  (the action of  $\mathbf{G}$  on X is free). Thus f is a closed immersion. By (1) it is étale and surjective. Therefore, f is an isomorphism.

**Remark 5.5.** We expect that Theorem 5.4 holds for prime spectra of strictly henselian rings.

Now we introduce sufficient condition for smoothness of geometric quotient in case of locally algebraic *k*-schemes.

**Corollary 5.6.** Suppose that **G** is a smooth algebraic group over k. Let  $q: X \to Y$  be a morphism of finite type between k-schemes locally of finite type. Assume that q is a uniform geometric quotient of X and x is a k-point of X with closed free orbit. Then q is smooth at x.

*Proof.* Since smoothness descent along faithfully flat morphisms, we may assume that k is algebraically closed. Let y = q(x). Then y is a k-point of Y. Now  $1_{\text{Spec }\widehat{\mathcal{O}_{Y,y}}} \times_k q$  is a geometric quotient and  $\widehat{\mathcal{O}_{Y,y}}$  is a complete local noetherian k-algebra with k as a residue field. Moreover, x is a k-point of  $\text{Spec }\widehat{\mathcal{O}_{Y,y}} \times_k X$  with a closed free orbit. By Theorem 5.4 we deduce that  $1_{\text{Spec }\widehat{\mathcal{O}_{Y,y}}} \times_k q$  is smooth. From descent for smoothness we infer that q is smooth at x.

**Definition 5.7.** Let  $q: X \to Y$  be a **G**-equivariant morphism into a k-scheme Y equipped with the trivial **G**-action. Suppose that q is faithfully flat, quasi-compact morphism and the square

$$\mathbf{G} \times_k X \xrightarrow{a} X$$

$$\operatorname{pr}_X \downarrow \qquad \qquad \downarrow q$$

$$X \xrightarrow{a} Y$$

is cartesian. Then *q* is a principal **G**-bundle.

Now we use Theorem 5.4 to describe principal **G**-bundles in the category of locally algebraic k-schemes.

**Theorem 5.8.** Suppose that **G** is a smooth algebraic group over k. Let  $q: X \to Y$  be a morphism of finite type between k-schemes locally of finite type. Then the following assertions are equivalent.

- (i) q is a universal geometric quotient and the action of G on X is free.
- (ii) q is a uniform geometric quotient and the action of G on X is free.
- (iii) q is a principal **G**-bundle.

*Proof.* Clearly (i)  $\Rightarrow$  (ii). Suppose that (ii) holds. Let  $\bar{k}$  be an algebraic closure of k. Then  $1_{\text{Spec}\bar{k}} \times_k q$ is a uniform quotient and the action of Spec  $\overline{k} \times_k \mathbf{G}$  on Spec  $\overline{k} \times_k X$  induced by the action of  $\mathbf{G}$  on X is free. Moreover, if  $1_{\operatorname{Spec} \overline{k}} \times_k q$  is a principal  $\operatorname{Spec} \overline{k} \times_k \mathbf{G}$ -bundle, then q is a  $\mathbf{G}$ -bundle. This follows from the observation that property of being a principal bundle descents along faithfuly flat and quasi-compact base extensions. Thus we may assume that k is algebraically closed. Next we pick a k-point y of Y and consider base change  $1_{\text{Spec }\widehat{\mathcal{O}_{Y,y}}} \times_Y q$ . This is a geometric quotient (because morphism Spec  $\widehat{\mathcal{O}_{Y,y}} \to Y$  is flat) and a morphism of finite type. Moreover, the action of **G** on Spec  $\mathcal{O}_{Y,y} \times_Y X$  is free. Since  $\mathcal{O}_{Y,y}$  is a complete noetherian k-algebra with residue field k, we derive by Theorem 5.4 that Spec  $\widehat{\mathcal{O}_{Y,y}} \times_Y q$  is isomorphic as a **G**-equivariant morphism with  $\operatorname{pr}_{\operatorname{Spec} \widetilde{\mathcal{O}_{Y,y}}}$ . By faithfuly flat descent for flat morphism we deduce that q is flat at every point in the fiber  $q^{-1}$  (Spec  $\mathcal{O}_{Y,y}$ ). Since y is an arbitrary k-point, it follows that q is flat at every point of X which specializes to a k-point. Every point of X is a generization of a k-point (X is locally of finite type and k is algebraically closed). Thus q is flat. It is also surjective (as it is a geometric quotient) and quasi-compact (it is of finite type). Therefore, it is faithfully flat and quasi-compact morphism. In order to obtain (iii) it remains to prove that the morphism  $\Phi : \mathbf{G} \times_k X \to X \times_Y X$ induced by a and  $\operatorname{pr}_X$  is an isomorphism. Note that it is a closed immersion (the action of  $\mathbf{G}$  on X is closed). Moreover,  $1_{\operatorname{Spec} \overline{\mathcal{O}_{Y,y}}} \times_Y \Phi$  is an isomorphism due to the fact that  $1_{\operatorname{Spec} \overline{\mathcal{O}_{Y,y}}} \times_Y q$  is isomorphic as a  $\mathbf{G}$ -equivariant morphism with  $\operatorname{pr}_{\operatorname{Spec} \overline{\mathcal{O}_{Y,y}}}$ . By faithfully flat descent we infer that  $1_{\text{Spec }\mathcal{O}_{Y,y}} \times_Y \Phi$  is an isomorphism. This holds for every k-point y in Y. Thus  $\Phi$  induces an isomorphism  $\mathcal{O}_{X\times_Y X,\Phi(z)} \to \mathcal{O}_{G\times_k X,z}$  for every k-point z of  $X\times_Y X$ . Hence a closed immersion  $\Phi$ is an isomorphism. This completes the proof of (ii)  $\Rightarrow$  (iii). Assume now that (iii) holds. Then the square

$$G \times_k X \xrightarrow{a} X$$

$$pr_X \downarrow \qquad \qquad \downarrow q$$

$$X \xrightarrow{q} Y$$

is cartesian and q is faithfully flat and quasi-compact. By Proposition 3.11 morphism  $\operatorname{pr}_X$  is a universal geometric quotient. According to Corollary 3.6 we derive that q is universal geometric quotient. Moreover, the cartesian square above shows that the morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by a and  $\operatorname{pr}_X$  is an isomorphism. Thus the action of  $\mathbf{G}$  on X is free. This is (i). Hence (iii)  $\Rightarrow$  (i) holds.

## 6. GOOD CATEGORICAL QUOTIENTS

In this section we fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ . We start by the following criterion for categorical quotients.

**Theorem 6.1.** Let  $q: X \to Y$  be a morphism into a k-scheme Y equipped with the trivial G-action. Assume that the following assertions hold.

- (1) q is **G**-equivariant.
- (2)  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q.
- **(3)** If Z is a **G**-stable closed subset of X, then q(Z) is a closed subset of Y.
- **(4)** If  $\{Z_i\}_{i\in I}$  is a family of closed **G**-stable subsets with the empty intersection, then the intersection  $\{q(Z_i)\}_{i\in I}$  is empty.

Then q is submersive and it is a categorical quotient of X.

*Proof.* Clearly q(X) is closed in Y. Hence  $V = Y \setminus q(X)$  is open. Moreover,  $q^{\#}: \mathcal{O}_{Y} \to q_{*}\mathcal{O}_{X}$  is a monomorphism of sheaves of k-algebras. Thus we have a monomorphism  $\mathcal{O}_{V} \hookrightarrow (q_{*}\mathcal{O}_{X})_{q^{-1}(V)}$ . We have  $(q_{*}\mathcal{O}_{X})_{q^{-1}(V)} = 0$  and hence  $\mathcal{O}_{V} = 0$ . This implies that  $V = \emptyset$ . Thus q is surjective. Suppose that Z is a subset of Y such that  $q^{-1}(Z)$  is a closed subset of X. Then  $q^{-1}(Z)$  is a G-stable closed subset and hence  $q(q^{-1}(Z))$  is closed. Note that  $q(q^{-1}(Z)) = Z$  because q is surjective. Thus Z is closed. This completes the proof that q is submersive.

Now we show that q is a categorical quotient of X. For this pick a **G**-equivariant morphism  $p: X \to Z$  where Z is a k-scheme with the trivial **G**-action. Consider open affine cover  $\{W_i\}_{i \in I}$  of Z. Then  $X \setminus p^{-1}(W_i)$  is a closed **G**-stable closed for  $i \in I$ . Define  $V_i = Y \setminus q(X \setminus p^{-1}(W_i))$  for each i. Thus  $V_i$  is an open subset of Y for every  $i \in I$ . Moreover, we have

$$\bigcap_{i\in I}X\smallsetminus p^{-1}(W_i)=\varnothing$$

and hence  $\{V_i\}_{i\in I}$  form an open cover of Y. Note that for every  $i\in I$  we have  $q^{-1}(V_i)\subseteq p^{-1}(V_i)$ . Consider the composition

$$\Gamma\left(W_{i},\mathcal{O}_{Z}\right) \xrightarrow{p^{\#}} \Gamma\left(p^{-1}(W_{i}),\mathcal{O}_{X}\right) \xrightarrow{f \mapsto f_{|q^{-1}(V_{i})}} \Gamma\left(q^{-1}(V_{i}),\mathcal{O}_{X}\right)$$

for every i in I. Since the action of  $\mathbf{G}$  on Z is trivial, we derive that the image of the morphism above consists of  $\mathbf{G}$ -invariant functions on  $q^{-1}(V_i)$ . This means that the morphism above factors uniquely through  $q_{V_i}^{\sharp}: \Gamma(V_i, \mathcal{O}_Y) \to \Gamma(q^{-1}(V_i), \mathcal{O}_X)$ . Since  $W_i$  is affine for every i in I, we obtain a unique morphism  $f_i: V_i \to W_i$  such that  $f_i \cdot q_{|q^{-1}(V_i)} = p_{|q^{-1}(V_i)}$  for each i. By construction the family  $\{f_i\}_{i\in I}$  glue to a morphism  $f: Y \to Z$  such that  $f \cdot q = p$ . This morphism is unique due to the fact that  $f_i$  are unique for every i. This finishes the proof of the fact that q is a categorical quotient of X.

**Definition 6.2.** Let  $q: X \to Y$  be a morphism into a k-scheme Y equipped with the trivial **G**-action. Suppose that q satisfies conditions (1)-(4) of Theorem 6.1. Then q is a good categorical quotient of X.

**Proposition 6.3.** Let  $q: X \to Y$  be a morphism into a k-scheme Y equipped with the trivial **G**-action. Assume that X is quasi-compact and the following assertions hold.

- (1) q is **G**-equivariant.
- **(2)**  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q.
- **(3)** If Z is a **G**-stable closed subset of X, then q(Z) is a closed subset of Y.
- **(4)** If  $Z_1$  and  $Z_2$  are closed **G**-stable subsets with the empty intersection, then  $q(Z_1) \cap q(Z_2) = \emptyset$ .

Then q is a good categorical quotient of X.

*Proof.* Suppose that  $\{Z_i\}_{i\in I}$  is a family of closed **G**-stable subsets with the empty intersection. Since X is quasi-compact, there exists a finite subset  $\{i_1,...,i_n\}\subseteq I$  such that the family  $\{Z_{i_1},...,Z_{i_n}\}$  has empty intersection. Then

$$\bigcap_{i\in I}q(Z_i)\subseteq\bigcap_{j=1}^nq(Z_{i_j})=\varnothing$$

according to (4). This implies that *q* is a good categorical quotient.

As in case of categorical and geometric quotients one can introduce the following notion.

**Definition 6.4.** A morphism  $q: X \to Y$  is a universal (uniform) good categorical quotient of X if for every (flat) morphism  $g: Y' \to Y$  of k-schemes a base change  $q': X' \to Y'$  of q along g is a good categorical quotient of X'.

**Corollary 6.5.** *If*  $q: X \to Y$  *is a uniform good categorical quotient, then it is universally submersive.* 

*Proof.* Let  $g: Y' \to Y$  be a morphism of k-schemes. Then we can factor g as a closed immersion  $Y' \to Z$  followed by a flat morphism  $Z \to Y$ . Since  $q' = 1_Z \times_Y q$  is a good categorical quotient, we derive that it is submersive by Theorem 6.1. Hence the restriction  $q'^{-1}(Y') \to Y'$  of q' to a closed subset is also submersive. Therefore,  $1_{Y'} \times_Y q$  is submersive.

**Theorem 6.6.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Then the following assertions are equivalent.

- (i) There exists an open cover V of Y such that for every V in V the restriction  $q^{-1}(V) \to V$  of q is a universal (uniform) good categorical quotient.
- (ii) q is a universal (uniform) good categorical quotient.
- (iii) For every affine k-scheme Y' and a (flat) morphism  $g: Y' \to Y$  of k-schemes a base change  $q': X' \to Y'$  of q along g is a good categorical quotient.
- (iv) There exists an open affine cover V of Y such that for every V in V the restriction  $q^{-1}(V) \to V$  of q is a universal (uniform) good categorical quotient.

For the proof we need the following.

**Lemma 6.6.1.** Let Y be a k-scheme with the trivial action of **G** and let  $q: X \to Y$  be a **G**-equivariant morphism. Suppose that there exists an open cover V of Y such that for every V in V the restriction  $q^{-1}(V) \to V$  of q is a good categorical quotient. Then q is a good categorical quotient.

*Proof of the lemma.* Pick a closed **G**-stable subset Z of X. Then  $q(Z) \cap V$  is closed in V for every  $V \in \mathcal{V}$ . Thus q(Z) is closed in Y. Suppose that  $\{Z_i\}_{i \in I}$  are closed **G**-stable subsets of X with empty intersection. Then

$$V \cap \bigcap_{i \in I} q(Z_i) = \emptyset$$

and hence the intersection of  $\{q(z_i)\}_{i\in I}$  is empty. According to Proposition 2.10 we derive that  $\mathcal{O}_Y$  is the sheaf of **G**-invariant functions for q. Thus q is a good categorical quotient.

*Proof of the theorem.* Implications (ii)  $\Rightarrow$  (iii) and (iv)  $\Rightarrow$  (v) are obvious.

We prove (i)  $\Rightarrow$  (ii). Suppose that (i) holds. Pick a (flat) morphism  $g: Y' \to Y$  and fix a cartesian square

$$X' \xrightarrow{g'} X$$

$$\downarrow^{q} \downarrow^{q} Y' \xrightarrow{g} Y$$

Then  $V' = \{g^{-1}(V) | V \in V\}$  is an open cover of Y' such that for every  $V \in V'$  the morphism  $q'^{-1}(V) \to V$  is a uniform categorical quotient. By Lemma 6.6.1 we derive that q' is a good categorical quotient. This is (ii).

Assume that (iii) holds. Pick an open affine subset V of Y. Consider a (flat) morphism  $g: V' \to V$  and pick a cartesian square

$$U' \xrightarrow{g'} q^{-1}(V)$$

$$\downarrow^{q_V} \qquad \qquad \downarrow^{q_V} \qquad \qquad \downarrow^{q_V}$$

where  $q_V: q^{-1}(V) \to V$  is the restriction of q. Then for every open affine subset W of V' the restriction  $q_{V'}^{-1}(W) \to W$  of  $q_{V'}$  is a universal (uniform) good categorical quotient according to (iii) (and the fact that  $W \to V'$  composed with g is flat). By Lemma 6.6.1 it follows that  $q_{V'}$  is a good categorical quotient. Thus  $q_V$  is a universal (uniform) good categorical quotient. This holds for every open affine subset V of Y. This is (iv) and hence (iii)  $\Rightarrow$  (iv) holds.

#### 7. AFFINE CASE

In this section we fix a k-scheme X equipped with an action of G determined by morphism  $a : G \times_k X \to X$ . We make the first important step towards existence of quotients by proving that good categorical quotients exists for affine k-schemes equipped with an action of geometrically reductive groups.

**Proposition 7.1.** Suppose that G is geometrically reductive group and X is an affine k-scheme. Let  $Z_1, Z_2$  be nonempty closed G-stable subsets of X such that  $Z_1 \cap Z_2 = \emptyset$ . Then there exists G-invariant regular function f on X such that  $f_{|Z_1} = 1$  and  $f_{|Z_2} = 0$ .

*Proof.* By [Monygham, 2020, Corollary 5.4] we may consider  $Z_1$  and  $Z_2$  as a closed **G**-stable subschemes of X. Since  $Z_1 \cap Z_2 = \emptyset$ , we have

$$\Gamma(Z_1 \cup Z_2, \mathcal{O}_X) = \Gamma(Z_1, \mathcal{O}_X) \times \Gamma(Z_2, \mathcal{O}_X)$$

In particular, there exists a regular invariant function

$$g \in \Gamma(Z_1, \mathcal{O}_X)^{\mathbf{G}} \times \Gamma(Z_2, \mathcal{O}_X)^{\mathbf{G}} = \Gamma(Z_1 \cup Z_2, \mathcal{O}_X)^{\mathbf{G}}$$

such that  $g_{\mid Z_1}$  = 1 and  $g_{\mid Z_2}$  = 0 . Consider the canonical morphism

$$\Gamma(X, \mathcal{O}_X)^{\mathbf{G}} \longrightarrow \Gamma(Z_1 \cup Z_2, \mathcal{O}_X)^{\mathbf{G}} = \Gamma(Z_1, \mathcal{O}_X)^{\mathbf{G}} \times \Gamma(Z_2, \mathcal{O}_X)^{\mathbf{G}}$$

According to [Monygham, 2021, Theorem 2.4] there exists  $f \in \Gamma(X, \mathcal{O}_X)$  and a positive integer r such that  $f_{|Z_1 \cup Z_2} = g^r$ . Then  $f_{|Z_1} = 1$  and  $f_{|Z_2} = 0$ .

**Theorem 7.2.** Suppose that X is an affine k-scheme and G is a geometrically reductive group. Let  $Y = \operatorname{Spec} \Gamma(X, \mathcal{O}_X)^G$  and let  $q: X \to Y$  be the canonical morphism. Then q is a uniform good categorical quotient of X. Moreover, the following assertions hold.

- **(1)** If X is of finite type over k, then Y is of finite type over k.
- **(2)** If **G** is linearly reductive, then q is a universal good categorical quotient of X.
- **(3)** If the action of G on X is closed, then q is a uniform geometric quotient.

For the proof we need to following results.

**Lemma 7.2.1.** Let **G** be an algebraic group which acts on Spec A for some k-algebra A. Fix a flat  $A^{\mathbf{G}}$ -algebra B. Then the canonical morphism  $B \to (A \otimes_{A^{\mathbf{G}}} B)^{\mathbf{G}}$  is an isomorphism of k-algebras.

*Proof of the lemma.* For every linear representation V of G we have a left exact sequence

$$0 \longrightarrow V^{\mathbf{G}} \longrightarrow V \xrightarrow{x \mapsto c(x) - 1 \otimes x} k[\mathbf{G}] \otimes_k V$$

where  $c: V \to k[G] \otimes_k V$  is the coaction. Now we denote by d the coaction on A. Thus we have left exact sequences

$$0 \longrightarrow A^{\mathbf{G}} \otimes_{A^{\mathbf{G}}} B \longrightarrow A \otimes_{A^{\mathbf{G}}} B \xrightarrow{x \otimes 1 \mapsto d(x) \otimes 1 - 1 \otimes x \otimes 1} k[\mathbf{G}] \otimes_k A \otimes_{A^{\mathbf{G}}} B$$

and

$$0 \longrightarrow (A \otimes_{A^{\mathbf{G}}} B)^{\mathbf{G}} \longrightarrow A \otimes_{A^{\mathbf{G}}} B \xrightarrow{x \otimes 1 \mapsto d(x) \otimes 1 - 1 \otimes x \otimes 1} k[\mathbf{G}] \otimes_k A \otimes_{A^{\mathbf{G}}} B$$

Note that  $A \otimes_{A^{\mathbf{G}}} B \ni x \otimes 1 \mapsto d(x) \otimes 1 \in k[\mathbf{G}] \otimes_k A \otimes_{A^{\mathbf{G}}} B$  is the coaction induced by c on the base change  $A \otimes_{A^{\mathbf{G}}} B$ . This implies that there is canonical isomorphism

$$B=A^{\mathbf{G}}\otimes_{A^{\mathbf{G}}}B\cong (A\otimes_{A^{\mathbf{G}}}B)^{\mathbf{G}}$$

**Lemma 7.2.2.** Let **G** be geometrically reductive group which acts on Spec A for some k-algebra A. If  $f_1, ..., f_n \in A^{\mathbf{G}}$  and

$$f \in \left(\sum_{i=1}^n A f_i\right) \cap A^{\mathbf{G}}$$

then there exists positive integer r such that

$$f^r \in \sum_{i=1}^n A^{\mathbf{G}} f_i$$

Moreover, if G is linearly reductive, then r can be chosen to be 1.

*Proof of the lemma.* Let  $d: A \to k[G] \otimes_k A$  be the coaction of G on A. The proof goes on induction on n. Write  $f = a_1 f_1 + ... + a_n f_n$  for  $a_1, ..., a_n \in A$ . Consider  $\mathfrak{a} = \operatorname{ann}(f_1) + A f_2 + ... + A f_n$ . This is a G-stable ideal in A. We show now that  $a_1$  is G-invariant modulo  $\mathfrak{a}$ . Indeed, we have

$$(1 \otimes f_1)(d(a_1) - 1 \otimes a_1) = d(f_1)d(a_1) - 1 \otimes f_1a_1 = d(f) - 1 \otimes f = 0$$

Hence

$$d(a_1) - 1 \otimes a_1 \in k[\mathbf{G}] \otimes_k \operatorname{ann}(f_1) \subseteq k[\mathbf{G}] \otimes_k \mathfrak{a}$$

and this shows that  $a_1$  is **G**-invariant modulo  $\mathfrak{a}$ . Therefore, according to [Monygham, 2021, Theorem 2.4] there exists positive integer r and  $a_1' \in A^{\mathbf{G}}$  such that  $a_1^r - a_1' \in \mathfrak{a}$ . Thus

$$f^r \in f_1^r a_1^r + A f_2 + \dots + A f_n = f_1^r a_1^r + A f_2 + \dots + A f_n$$

Now if n = 1, then we have  $f^r = f_1^r a_1' \in A^{\mathbf{G}} f_1$  and the assertion holds. On the other hand if  $n \ge 2$ , then we can apply inductive hypothesis to

$$f^r - f_1^r a_1' \in (A f_2 + ... + A f_n) \cap A^G$$

and obtain that

$$(f^r - f_1^r a_1')^d \in A^{\mathbf{G}} f_2 + \dots + A^{\mathbf{G}} f_n$$

for some positive integer d. Then

$$f^{rd} \in A^{\mathbf{G}} f_1 + A^{\mathbf{G}} f_2 + \dots + A^{\mathbf{G}} f_n$$

and the assertion holds.

**Lemma 7.2.3.** Let **G** be geometrically reductive group which acts on Spec A for some k-algebra A. Then the morphism Spec  $A \to \text{Spec } A^G$  is surjective.

*Proof of the lemma.* Pick a prime ideal  $\mathfrak{p} \in \operatorname{Spec} A^{\mathbf{G}}$ . Consider  $f \in A\mathfrak{p} \cap A^{\mathbf{G}}$ . Then there exist  $f_1, ..., f_n \in \mathfrak{p}$  such that

$$f\in \left(Af_1+\ldots+Af_n\right)\cap A^{\mathbf{G}}$$

By Lemma 7.2.2 we have

$$f^r \in A^{\mathbf{G}} f_1 + \dots + A^{\mathbf{G}} f_n \subseteq \mathfrak{p}$$

for some positive integer r. Since  $\mathfrak p$  is a prime ideal, we derive that  $f \in \mathfrak p$ . Thus  $A\mathfrak p \cap A^G = \mathfrak p$ . Thus we have an injective morphisms  $A^G/\mathfrak p \hookrightarrow A/A\mathfrak p$  of k-algebras. This implies that the morphism  $k(\mathfrak p) \to k(\mathfrak p) \otimes_{A^G} A$  is also injective, where  $k(\mathfrak p)$  is a residue field of  $\mathfrak p$  in  $A^G$ . We infer that the fiber of Spec  $A \to \operatorname{Spec} A^G$  is nonempty.

**Lemma 7.2.4.** Let **G** be geometrically reductive group which acts on Spec A for some k-algebra A. Suppose that  $\mathfrak{a}$  is an ideal in  $A^{\mathbf{G}}$ . Then  $(A/A\mathfrak{a})^{\mathbf{G}}$  is canonically isomorphic with  $A^{\mathbf{G}}/\mathfrak{a}$ .

*Proof of the lemma.* Lemma 7.2.2 shows that  $A\mathfrak{a} \cap A^G = \mathfrak{a}$ . Since **G** is linearly reductive, we have a canonical identification

$$(A/A\mathfrak{a})^{\mathbf{G}} = A^{\mathbf{G}}/(A\mathfrak{a})^{\mathbf{G}} = A^{\mathbf{G}}/A\mathfrak{a} \cap A^{\mathbf{G}} = A^{\mathbf{G}}/\mathfrak{a}$$

*Proof of the theorem.* Since X is quasi-compact, we may verify conditions of Proposition 6.3. First let us denote by A the k-algebra of global regular functions  $\Gamma(X, \mathcal{O}_X)$ . Suppose that  $V \subseteq \operatorname{Spec} A^G = Y$  is an open affine subset. Then  $B = \Gamma(V, \mathcal{O}_Y)$  is a flat  $A^G$ -algebra and by Lemma 7.2.1 we have canonical isomorphism

$$B \cong (A \otimes_{A^{\mathbf{G}}} B)^{\mathbf{G}}$$

This implies that  $\Gamma(V, \mathcal{O}_Y) \cong \Gamma(q^{-1}(V), \mathcal{O}_X)^{\mathbf{G}}$  and hence  $\mathcal{O}_Y$  is the sheaf of **G**-invariants for q. Fix now a closed **G**-stable subset Z of X. By [Monygham, 2020, Corollary 5.4] there exists a **G**-stable ideal  $\mathfrak{a} \subseteq A$  such that its vanishing set is equal to Z. Consider a commutative square

$$\operatorname{Spec} A/\mathfrak{a} \longrightarrow \operatorname{Spec} A$$

$$\downarrow \qquad \qquad \downarrow$$

$$\operatorname{Spec} (A/\mathfrak{a})^{G} \longrightarrow \operatorname{Spec} A^{G}$$

with canonically defined arrows. Note that Spec  $A/\mathfrak{a} \to \operatorname{Spec}(A/\mathfrak{a})^G$  is surjective (Lemma 7.2.3) and according to [Monygham, 2021, Theorem 2.4] morphism

Spec 
$$(A/\mathfrak{a})^{\mathbf{G}} \to \operatorname{Spec} A^{\mathbf{G}}/\mathfrak{a} \cap A^{\mathbf{G}}$$

is surjective. Thus the set-theoretic image of Spec  $A/\mathfrak{a}$  under the map Spec  $A \to \operatorname{Spec} A^{\mathbf{G}}$  is a closed subset given by Spec  $A^{\mathbf{G}}/\mathfrak{a} \cap A^{\mathbf{G}}$ . Hence q(Z) is a closed subset of Y.

Fix now two closed **G**-stable subsets  $Z_1, Z_2$  and assume that  $Z_1 \cap Z_2 = \emptyset$ . We claim that  $q(Z_1) \cap q(Z_2) = \emptyset$ . For this we may assume that  $Z_1, Z_2$  are both nonempty. Proposition 7.1 implies that there exists  $f \in \Gamma(X, \mathcal{O}_X)^{\mathbf{G}}$  such that  $f_{|Z_1} = 1$  and  $f_{|Z_2} = 0$ . Then f viewed as a function on Y satisfies  $f_{|q(Z_1)} = 1$  and  $f_{|q(Z_2)} = 0$ . Thus  $q(Z_1) \cap q(Z_2) = \emptyset$ .

This completes the proof that q is a good categorical quotient. Lemma 7.2.1 and Theorem 6.6 imply that q is a uniform good categorical quotient.

If X is of finite type over k, then by [Monygham, 2021, Theorem 3.1] we deduce that Y which is the prime spectrum of  $\Gamma(X, \mathcal{O}_X)^G$  is of finite type over k.

If **G** is linearly reductive, then by Lemmas 7.2.1, 7.2.4 and Theorem 6.6 we deduce that q is a universal good categorical quotient.

Suppose now that the action of **G** on *X* is closed. Pick a point  $z \in X \times_Y X$ . There exists an algebraically closed extension *K* of *k* such that there is a *K*-point  $\overline{z}$  with z as the underlying point. Suppose that  $\overline{x}_1 = \operatorname{pr}_X(\overline{z})$  and  $\overline{x}_2 = a(\overline{z})$ . Consider orbit morphisms

$$o_{\overline{x}_1}, o_{\overline{x}_2} : \mathbf{G} \times_k \operatorname{Spec} K \to X \times_k \operatorname{Spec} K$$

Then their set-theoretic images are closed **G**-stable subsets  $o_1, o_2$  of  $X \times_k \operatorname{Spec} K$ . Next q is a uniform good categorical quotient. Hence also  $\overline{q} = q \times_k 1_{\operatorname{Spec} K}$  is a good categorical quotient. If  $o_1 \cap o_2 = \emptyset$ , then  $\overline{q}(o_1) \cap \overline{q}(o_2) = \emptyset$ . This is impossible since

$$\overline{q}(\overline{x}_1) = \overline{q}(\operatorname{pr}_X(\overline{z})) = \overline{q}(a(\overline{z})) = \overline{q}(\overline{x}_2)$$

Thus  $o_1 \cap o_2 \neq \emptyset$ . Then there exists fields extension  $K \subseteq L$  such that  $o_1 \cap o_2$  contains an L-point  $\tilde{x}$  and both morphisms  $o_{\overline{x}_1}$  and  $o_{\overline{x}_2}$  induce surjections on L-points. Let  $\tilde{x}_1, \tilde{x}_2$  be L-points induced by  $\overline{x}_1, \overline{x}_2$  and  $K \subseteq L$ . Now there exist  $g_1, g_2 \in \mathbf{G}(L)$  such that  $g_1 \cdot \tilde{x}_1 = \tilde{x} = g_2 \cdot \tilde{x}_2$ . Hence for  $g = g_2^{-1} \cdot g_1 \in \mathbf{G}(L)$  we have  $\tilde{x}_2 = g \cdot \tilde{x}_1$ . Next let  $\tilde{z}$  be an L-point of  $X \times_Y X$  induced by  $\overline{z}$  and  $K \subseteq L$ . Then  $\tilde{z} = (\tilde{x}_2, \tilde{x}_1)$  and since for  $(g, \tilde{x}_1) \in \mathbf{G}(L) \times X(L)$  we have  $(g \cdot \tilde{x}_1, \tilde{x}_1) = (\tilde{x}_2, \tilde{x}_1) = \tilde{z}$ , we deduce that the image of the morphism  $\mathbf{G} \times_k X \to X \times_Y X$  induced by  $(a, \operatorname{pr}_X)$  contains z. Thus the morphism  $\mathbf{G} \times_k X \to X \times_Y X$  is surjective and hence q is a geometric quotient. According to Lemma 7.2.1 and Theorem 3.10 we derive that q is a uniform geometric quotient.

# 8. QUOTIENTS DETERMINED BY LINEARIZATION

We start by discussing some preliminary result concerning **G**-linearizations of quasi-coherent sheaves. We assume in this section that **G** is an affine group scheme over k. We fix a k-scheme X equipped with an action of **G** determined by morphism  $a : \mathbf{G} \times_k X \to X$ .

**Proposition 8.1.** Let  $\mathcal{F}$  be a quasi-coherent sheaf on X and let  $\tau: a^*\mathcal{F} \to \operatorname{pr}_X^*\mathcal{F}$  be a G-linearization of  $\mathcal{F}$ . Suppose that X is quasi-compact and semiseparated. Then the morphism

$$\Gamma(X, \mathcal{F}) \ni s \mapsto \tau(a^*s) \in \Gamma(\mathbf{G} \times_k X, \operatorname{pr}_X^* \mathcal{F}) = k[\mathbf{G}] \otimes_k \Gamma(X, \mathcal{F})$$

is a coaction of G on  $\mathcal{F}$ .

*Proof.* We denote the morphism in the statement by c. Fix  $s \in \Gamma(X, \mathcal{F})$ . Write

$$c(s) = \sum_{i=1}^{n} a_i \otimes s_i \in k[\mathbf{G}] \otimes_k \Gamma(X, \mathcal{F})$$

Then

$$(1_{k[G]} \otimes_{k} c)(c(s)) = \sum_{i=1}^{n} a_{i} \otimes c(s_{i}) = \sum_{i=1}^{n} a_{i} \otimes \tau(a^{*}s_{i}) = (\operatorname{pr}_{23}^{*}\tau) \left(\sum_{i=1}^{n} a_{i} \otimes a^{*}s_{i}\right) =$$

$$= (\operatorname{pr}_{23}^{*}\tau) \left(\sum_{i=1}^{n} (1_{G} \times_{k} a)^{*} (a_{i} \otimes s_{i})\right) = (\operatorname{pr}_{23}^{*}\tau \cdot (1_{G} \times_{k} a)^{*}\tau) \left((1_{G} \times_{k} a)^{*} a^{*}s\right) =$$

$$= ((\mu \times_{k} 1_{X})^{*}\tau) \left((\mu \times_{k} 1_{X})^{*} a^{*}s\right) = (\mu \times_{k} 1_{X})^{*} (\tau(a^{*}s)) = (\Delta \otimes_{k} 1_{\Gamma(X,\mathcal{F})}) (c(s))$$

where  $\Delta : k[G] \to k[G] \otimes_k k[G]$  is the comultiplication. Moreover, we also have

$$(\xi \otimes_k 1_{\Gamma(X,\mathcal{F})}) (c(s)) = (e \times_k 1_X)^* (\tau(a^*s)) = ((e \times_k 1_X)^* \tau) ((e \times_k 1_X)^* a^*s) =$$

$$= ((e \times_k 1_X)^* a^*s) = 1 \otimes s$$

where  $\xi : k[\mathbf{G}] \to k$  is the counit. These imply that c is the coaction of  $k[\mathbf{G}]$  on the space of global sections of  $\mathcal{F}$ .

**Definition 8.2.** Let  $\mathcal{F}$  be a quasi-coherent sheaf on X and let  $\tau: a^*\mathcal{F} \to \operatorname{pr}_X^*\mathcal{F}$  be a **G**-linearization of  $\mathcal{F}$ . Suppose that X is quasi-compact and semiseparated. Then by Proposition 8.1 above  $\Gamma(X,\mathcal{F})$  is a linear representation of **G**. We call it *the linear representation induced by* **G**-linearization  $\tau$ .

Now we study properties of linear representations on global sections of line bundles with G-linearization.

**Proposition 8.3.** Suppose that X is quasi-compact and semiseparated. Let  $\mathcal{L}$  be a locally free sheaf of rank one on X and let  $\tau: a^*\mathcal{L} \to \operatorname{pr}_X^*\mathcal{L}$  be a G-linearization of  $\mathcal{L}$ . Then the following assertions hold.

(1) If  $s \in \Gamma(X, \mathcal{L})$  is **G**-invariant with respect to the structure of linear representation of **G** induced by  $\tau$ , then the open subscheme

$$X_s = \left\{ x \in X \,\middle|\, s(x) \neq 0 \right\}$$

of X is **G**-stable.

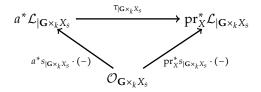

**(2)** If  $t, s \in \Gamma(X, \mathcal{L})$  are **G**-invariant with respect to the structure of linear representation of **G** induced by  $\tau$ , then the regular function  $\frac{t}{s} \in \Gamma(X_s, \mathcal{O}_X)$  is **G**-invariant.

*Proof.* Suppose that  $s \in \Gamma(X, \mathcal{L})$  is **G**-invariant with respect to the structure of linear representation of **G** induced by  $\tau$ . Then  $\tau(a^*s) = \operatorname{pr}_X^*s$ . Since  $\tau$  is an isomorphism of line bundles on  $\mathbf{G} \times_k X$ , nonvanishing sets of  $a^*s \in \Gamma(\mathbf{G} \times_k X, a^*\mathcal{L})$  and  $\operatorname{pr}_X^*s \in \Gamma(\mathbf{G} \times_k X, \operatorname{pr}_X^*\mathcal{L})$  coincide. Next the nonvanishing set of  $a^*s$  is  $a^{-1}(X_s)$ . On the other hand the nonvanishing set of  $\operatorname{pr}_X^*s$  is  $\operatorname{pr}_X^{-1}(X_s)$ . Therefore,  $a^{-1}(X_s) = \operatorname{pr}_X^{-1}(X_s)$  and hence  $X_s$  is open **G**-stable subscheme of X. This completes the proof of **(1)**.

Suppose that  $t,s \in \Gamma(X,\mathcal{L})$  are **G**-invariant. Clearly  $(\mathcal{O}_X)_{|X_s} \to \mathcal{L}_{|X_s}$  given by multiplication by s is an isomorphism. Recall that  $\frac{t}{s}$  is a unique element  $r \in \Gamma(X_s,\mathcal{O}_X)$  such that  $r \cdot s_{|X_s|} = t_{|X_s|}$ . Since  $X_s$  is **G**-invariant, r is **G**-invariant if

$$a^*r = pr_{\mathbf{v}}^*r$$

Since *s* is **G**-invariant, we have a commutative triangle

in which all morphisms are isomorphisms. By G-invariance of s and t we have

$$\operatorname{pr}_{X}^{*} s_{|\mathbf{G} \times_{k} X_{s}} \cdot a^{*} r = \tau \left( a^{*} s_{|\mathbf{G} \times_{k} X_{s}} \right) \cdot a^{*} r = \tau \left( a^{*} s_{|\mathbf{G} \times_{k} X_{s}} \cdot a^{*} r \right) =$$

$$= \tau \left( a^{*} t_{|\mathbf{G} \times_{k} X_{s}} \right) = \operatorname{pr}_{X}^{*} t_{|\mathbf{G} \times_{k} X_{s}} = \operatorname{pr}_{X}^{*} s_{|\mathbf{G} \times_{k} X_{s}} \cdot \operatorname{pr}_{X}^{*} r$$

and hence  $a^*r = \operatorname{pr}_X^*r$ . This finishes the proof of (2).

The following notion introduced by Mumford in [Mumford et al., 1994] is fundamental.

**Definition 8.4.** Let  $\mathcal{L}$  be a locally free sheaf of rank one on X and let  $\tau: a^*\mathcal{L} \to \operatorname{pr}_X^*\mathcal{L}$  be a **G**-linearization of  $\mathcal{L}$ . Consider a point x in X. Then we say that:

- (1) x is semistable with respect to  $\tau$  if there exists a **G**-invariant section  $s \in \Gamma(X, \mathcal{L}^{\otimes n})$  with respect to  $\tau^{\otimes n}$  for some n such that  $X_s$  is affine and contains x.
- (2) x is stable with respect to  $\tau$  if there exists a **G**-invariant section  $s \in \Gamma(X, \mathcal{L}^{\otimes n})$  with respect to  $\tau^{\otimes n}$  for some n such that  $X_s$  is affine, contains x and the action of **G** on  $X_s$  is closed.

We also denote by

$$X^{ss}(\tau), X^{s}(\tau)$$

sets of semistable and stable points of X with respect to  $\tau$ , respectively.

**Theorem 8.5.** Suppose that **G** is geometrically reductive and X is of finite type over k. Let  $\mathcal{L}$  be a line bundle on X which admits a **G**-linearization  $\tau: a^*\mathcal{L} \to \operatorname{pr}_X^*\mathcal{L}$ . Then there exists a uniform good categorical quotient  $q: X^{ss}(\tau) \to Y$  of  $X^{ss}(\tau)$  by **G**. Moreover, the following assertions hold.

- **(1)** q is affine, universally submersive and Y is of finite type over k.
- (2) There exists an ample locally free sheaf of rank onereboot  $\mathcal{M}$  on Y such that  $q^*\mathcal{M} = \mathcal{L}^{\otimes n}$  for some
- (3) There exists an open subscheme  $\tilde{Y}$  of Y such that  $q^{-1}(\tilde{Y}) = X^s(\tau)$  and the morphism  $X^s(\tau) \to \tilde{Y}$  induced by q is a uniform geometric quotient of  $X^s(\tau)$  by G.

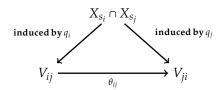

*Proof.* We may fix positive integer n such that there is a family of **G**-invariant (with respect to linear representation induced by  $\tau^{\otimes n}$ ) global sections  $s_1,...,s_N \in \Gamma(X,\mathcal{L}^{\otimes n})$  with the property that  $X_{s_i}$  is affine for  $1 \le i \le N$  and

$$X^{ss}(\tau) = \bigcup_{i=1}^{N} X_{s_i}$$

This follows from the fact that X is quasi-compact. According to Theorem 7.2 for every i there exists an affine scheme  $V_i$  of finite type over k with the trivial **G**-action and a **G**-equivariant morphism  $q_i: X_{s_i} \to V_i$  which is a uniform good categorical quotient of  $X_{s_i}$ . Fix now  $1 \le i, j \le n$ . Then  $\frac{s_i}{s_i}$  is a **G**-invariant function on  $X_{s_i}$  by Proposition 8.3. Thus it induces a function  $f_{ij}$  on  $V_i$ . Consider now

$$V_{ij} = \left\{ y \in V_i \,|\, f_{ij}(y) \neq 0 \right\}$$

Then  $V_{ij}$  is an open subset of  $V_i$ . Note that  $q_i^{-1}(V_{ij})$  is a nonvanishing set of  $\frac{s_j}{s_i}$  and hence it is equal to  $X_{s_i} \cap X_{s_j}$ . Since both  $q_i$  and  $q_j$  are uniform good categorical quotients, we derive that their restrictions  $X_{s_i} \cap X_{s_j} \to V_{ij}$  and  $X_{s_i} \cap X_{s_j} \to V_{ji}$  are categorical quotients. This implies that there exists a unique isomorphism  $\theta_{ij}: V_{ij} \to V_{ji}$  of k-schemes such that the triangle

is commutative. Isomorphisms  $\theta_{ij}: V_{ij} \to V_{ji}$  for pairs i,j of elements of  $\{1,...,N\}$  satisfy cocycle condition. Indeed, this follows by their uniqueness. Hence one can glue  $V_i$  to a scheme Y of finite type over k. Moreover, morphisms  $q_i$  for  $i \in \{1,...,N\}$  give rise to a morphism  $q: X^{ss}(\tau) \to Y$  such that  $q^{-1}(V_i) = X_{s_i}$  and the restriction of q to  $X_{s_i} \to V_i$  is equal to  $q_i$  for every i. According to Theorem 6.6 we derive that q is a uniform good categorical quotient of X. Moreover, q is affine and by Corollary 6.5 it is universally submersive. This completes the proof of the main assertion and (1).

Now we prove **(2)**. Pick three indices  $1 \le i, j, r \le N$ . Then  $f_{jr} \cdot f_{ij} = f_{ir}$  on an open subset  $V_i \cap V_j \cap V_r$  of Y. Hence  $f_{ij} : \mathcal{O}_{V_i \cap V_j} \to \mathcal{O}_{V_i \cap V_j}$  for  $i, j \in \{1, ..., N\}$  glue to a locally free sheaf of rank one  $\mathcal{M}$  on Y. Since  $q^\#(f_{ij}) = \frac{s_j}{s_i} \in \Gamma(X_{s_i}, \mathcal{O}_X)$  for every pair i, j, we derive that  $q^*\mathcal{M} = \mathcal{L}^{\otimes n}$ . Note also that  $f_{ji} \in \Gamma(V_j, \mathcal{O}_Y)$  for  $j \in \{1, ..., N\}$  give rise to a global section  $t_i$  of  $\mathcal{M}$ .
