#### CATEGORIES OF PRESHEAVES

#### 1. Introduction – set theoretical background

These notes deal with properties of categories of presheaves. For some arguments and also for the underlying set-theoretic setup we use Grothendieck universes [ML98, page 22]. This implies that our arguments rely on stronger foundational assumptions than the usual Zermelo-Frankel axioms. Grothendieck universes can be defined within Zermelo-Frankel set theory as follows.

**Definition 1.1.** Let *U* be a set. We say that *U* is *Grothendieck universe* if the following conditions are satisfied.

- (1) The set  $\omega$  of finite ordinals in the sense of von Neumann is an element of U.
- (2) If  $y \in U$  and  $x \in y$ , then  $y \in U$ .
- (3) If  $x \in U$ , then  $\mathcal{P}(x) \in U$  and  $\bigcup x \in U$ .
- **(4)** If  $x \in U$ ,  $y \subseteq U$  and  $f : x \to y$  is surjective, then  $y \in U$ .

If U is a Grothendieck universe, then the pair  $(U, \epsilon)$  forms a model for Zermelo-Frankel theory. This implies that the existence of Grothendieck universes is independent from Zermelo-Frankel axioms. In this notes we extend the usual Zermelo-Frankel system by adding the following Tarski axiom.

Every set is an element of some Grothendieck universe.

This new formal system is called *Tarski-Grothendieck set theory*. Let U be a Grothendieck universe. We denote by  $\mathbf{Set}_U$  a category whose objects are elements of U and whose morphisms are maps of sets.

**Definition 1.2.** Let U be a Grothendieck universe. A category C is U-small if classes of objects and morphisms of C are members of U.

**Definition 1.3.** Let U be a Grothendieck universe. A category  $\mathcal{C}$  is *locally U-small* if for any pair X, Y of objects of  $\mathcal{C}$  we have  $\operatorname{Mor}_{\mathcal{C}}(X,Y) \in U$ .

Throughout this notes we fix a Grothendieck universe U. Elements of U are called sets. We use term *class* for arbitrary sets (also these ones outside U). We denote **Set**<sub>U</sub> by **Set**. By (locally) small category we mean (locally) U-small category.

# 2. Creation of limits and colimits

**Definition 2.1.** Let  $F: \mathcal{C} \to \mathcal{X}$ ,  $D: I \to \mathcal{C}$  be functors. Suppose that  $(X, \{f_i\}_{i \in I})$  is a cone in  $\mathcal{X}$  for the composition  $F \cdot D$ . We say that a cone  $(Z, \{g_i\}_{i \in I})$  in  $\mathcal{C}$  for D is a lift of  $(X, \{f_i\}_{i \in I})$  if F(Z) = X and  $F(g_i) = f_i$  for every  $i \in I$ .

**Definition 2.2.** Let  $F: \mathcal{C} \to \mathcal{X}$ ,  $D: I \to \mathcal{C}$  be functors. We say that F *creates limits for* D if every limiting cone for  $F \cdot D$  has a unique lift to a cone for D and this lift is a limiting cone for D.

**Definition 2.3.** Let  $F : \mathcal{C} \to \mathcal{X}$  be a functor. We say that:

- **(1)** *F* creates limits if *F* creates limits for all functors  $D: I \to C$ .
- **(2)** *F* creates small limits if *F* creates limits for all functors  $D: I \to \mathcal{C}$  with *I* being small category.

(3) *F* creates finite limits if *F* creates limits for all functors  $D: I \to C$  with *I* being category with finitely many objects and arrows.

Some extra material on creation of limits can be found in [ML98, V.1]. By the usual arrow inverting one defines the notion of creation of colimits.

Now we prove an important result. First we need to introduce some notation. Suppose that  $\mathcal C$  and  $\mathcal X$  are categories. Then we denote by  $\operatorname{Fun}(\mathcal C,\mathcal X)$  the category with functors  $\mathcal C \to \mathcal X$  as objects and natural transformations between them as morphisms. We also denote by  $|\mathcal C|$  the category having the same objects as  $\mathcal C$  but with only identities as a morphism. There exists the canonical functor  $|\mathcal C| \to \mathcal C$  that induces identity map on objects. The next result describes limits and colimits in functor categories.

**Theorem 2.4.** Let C, X be a categories. Then the functor  $Fun(C,X) \to Fun(|C|,X)$  induced by the precomposition with the functor  $|C| \to C$  creates all limits and colimits.

*Proof.* We prove that this functor creates limits. Creation of colimits can be handled similarly. Let I be a category. For every object i in I consider a functor  $F_i:\mathcal{C}\to\mathcal{X}$  and for every arrow  $\alpha:i\to j$  in I consider a natural transformation  $F_\alpha:F_i\to F_j$ . Suppose that these data gives rise to a functor  $I\to \operatorname{Fun}(\mathcal{C},\mathcal{X})$ . Each limiting cone over the composition of  $I\to \operatorname{Fun}(\mathcal{C},\mathcal{X})$  and  $\operatorname{Fun}(\mathcal{C},\mathcal{X})\to \operatorname{Fun}(|\mathcal{C}|,\mathcal{X})$  consists of a family of objects  $\big\{F(X)\big\}_{X\in\mathcal{C}}$  of  $\mathcal{X}$  parametrized by objects of  $\mathcal{C}$  and a family  $\big\{f_{i,X}\big\}_{i\in I,X\in\mathcal{C}}$  of arrows in  $\mathcal{X}$  parametrized by objects of  $I\times\mathcal{C}$  such that the following assertion hold.

(\*) For every  $X \in \mathcal{C}$  a pair  $(F(X), \{f_{i,X}\}_{i \in I})$  is a limiting cone for a functor  $I \to \mathcal{X}$  given by  $i \mapsto F_i(X)$  and  $\alpha \mapsto F_\alpha(X)$  for any object i and arrow  $\alpha$  in I.

We now show that there exists a unique lift of a pair  $(\{F(X)\}_{X \in \mathcal{C}}, \{f_{i,X}\}_{i \in I, X \in \mathcal{C}})$  to a cone  $(F, \{f_i\}_{i \in I})$  over the functor  $I \to \mathbf{Fun}(\mathcal{C}, \mathcal{X})$  described by data  $(\{F_i\}_{i \in I}, \{F_\alpha\}_{\alpha \in \mathbf{Mor}(I)})$ . For this pick an arrow  $f: X \to Y$ . Then by (\*) there exists a unique arrow  $F(f): F(X) \to F(Y)$  such that every square

$$F(Y) \xrightarrow{f_{i,Y}} F_{i}(Y)$$

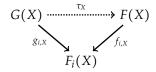

$$F(f) \qquad \qquad \uparrow_{F_{i}(f)}$$

$$F(X) \xrightarrow{f_{i,X}} F_{i}(X)$$

for every  $i \in I$  is commutative. Suppose that  $f: X \to Y$  and  $g: Y \to Z$  are arrows in C. Then

$$f_{i,Z} \cdot F(g \cdot f) = F_i(g \cdot f) \cdot f_{i,X} = F_i(g) \cdot F_i(f) \cdot f_{i,X} = F_i(g) \cdot f_{i,Y} \cdot F(f) = f_{i,Z} \cdot F(g) \cdot F(f)$$

According to (\*) we deduce that  $F(g \cdot f) = F(g) \cdot F(f)$ . Similarly we prove that  $F(1_X) = 1_{F(X)}$ . Hence there exists a unique functor  $F: \mathcal{C} \to \mathcal{X}$  that extends object mapping  $\{F(X)\}_{X \in \mathcal{C}}$  and such that  $\{f_i: F \to F_i\}_{i \in I}$  becomes a collection of natural transformations of functors. Therefore,  $(F, \{f_i\}_{i \in I})$  is a unique lift of  $(\{F(X)\}_{X \in \mathcal{C}}, \{f_{i,X}\}_{i \in I, X \in \mathcal{C}})$  to a cone over the functor  $I \to \mathbf{Fun}(\mathcal{C}, \mathcal{X})$  described by data  $(\{F_i\}_{i \in I'}, \{F_{\alpha}\}_{\alpha \in \mathbf{Mor}(I)})$ . Now we prove that the cone  $(F, \{f_i\}_{i \in I})$  is limiting. For this assume that  $(G, \{g_i\}_{i \in I})$  is a cone over the functor  $I \to \mathbf{Fun}(\mathcal{C}, \mathcal{X})$  described by data  $(\{F_i\}_{i \in I'}, \{F_{\alpha}\}_{\alpha \in \mathbf{Mor}(I)})$ . By (\*) we derive that for every  $X \in \mathcal{C}$  there exists a unique morphism  $\tau_X: G(X) \to F(X)$  such that

It suffices to verify that a collection  $\{\tau_X\}_{X\in\mathcal{C}}$  is a natural transformation of functors  $G\to F$ . For this pick  $f:X\to Y$ . Then

$$f_{i,Y} \cdot F(f) \cdot \tau_X = F_i(f) \cdot f_{i,X} \cdot \tau_X = F_i(f) \cdot g_{i,X} = g_{i,Y} \cdot G(f) = f_{i,Y} \cdot \tau_Y \cdot G(f)$$

for every  $i \in I$ . According to (\*) we deduce that  $F(f) \cdot \tau_X = \tau_Y \cdot G(f)$ . Since f is arbitrary, we derive that  $\{\tau_X\}_{X \in \mathcal{C}}$  is a natural transformation of functors  $G \to F$ .

Let C, X be categories. For every object  $X \in C$  we denote by  $\operatorname{ev}_X : \operatorname{Fun}(C, X) \to X$  the functor that sends  $F \in \operatorname{Fun}(C, X)$  to F(X) and  $f : F \to G$  in  $\operatorname{Fun}(C, X)$  to  $f_X : F(X) \to G(X)$ .

**Corollary 2.5.** Let C,  $\mathcal{X}$  and I be categories and let  $D: I \to \mathbf{Fun}(C, \mathcal{X})$  be a functor. Suppose that for every  $X \in C$  the functor  $\mathbf{ev}_X \cdot D: I \to \mathcal{X}$  admits a limit (colimit). Then D admits a limit (colimit). Moreover, suppose that  $(F, \{f_i\}_{i \in I})$  is a cone (cocone) over D. Then the following are equivalent.

- (i)  $(F, \{f_i\}_{i \in I})$  is a limiting cone (colimiting cocone) over D.
- (ii)  $(F, \{f_i\}_{i \in I})$  is a cone (cocone) over D and for every  $X \in C$  the pair  $(F(X), \{f_{i,X}\}_{i \in I})$  is a limiting cone (colimiting cocone) over  $ev_X \cdot D$ .

*Proof.* The assumption that for every  $X \in \mathcal{C}$  the functor  $\operatorname{ev}_X \cdot D : I \to \mathcal{X}$  admits a limit (colimit) implies that the composition of D with the functor  $\operatorname{Fun}(\mathcal{C},\mathcal{X}) \to \operatorname{Fun}(|\mathcal{C}|,\mathcal{X})$  induced by the canonical functor  $|\mathcal{C}| \to \mathcal{C}$  admits a limit (colimit). Now by Theorem 2.4 we derive that the functor  $\operatorname{Fun}(\mathcal{C},\mathcal{X}) \to \operatorname{Fun}(|\mathcal{C}|,\mathcal{X})$  creates limits and colimits. Hence D admits a limit (colimit). More precisely there exists a limiting cone (colimiting cocone)  $(F,\{f_i\}_{i\in I})$  over D such that for every  $X \in \mathcal{C}$  the pair  $(F(X),\{f_{i,X}\}_{i\in I})$  is a limiting cone (colimiting cocone) over  $\operatorname{ev}_X \cdot D$ . Since any two limiting cones (colimiting cocones) over given functor are isomorphic, we deduce that (i) ⇒ (ii). On the other hand if  $(F,\{f_i\}_{i\in I})$  is a cone (cocone) over D and for every  $X \in \mathcal{C}$  the pair  $(F(X),\{f_{i,X}\}_{i\in I})$  is a limiting cone (colimiting cocone) over  $\nabla V = \nabla V$ 

## 3. Presheaves

**Definition 3.1.** Let  $\mathcal{C}$  be a locally small category. We denote by  $\widehat{\mathcal{C}}$  the category  $\mathbf{Fun}(\mathcal{C}^{\mathrm{op}},\mathbf{Set})$  and we call it *the category of presheaves on*  $\mathcal{C}$ .

**Definition 3.2.** Let  $\mathcal{C}$  be a locally small category. For every object  $X \in \mathcal{C}$  we define  $h_X = \operatorname{Mor}_{\mathcal{C}}(-, X)$ . We call it *the presheaf represented by* X. Next for every morphism  $f: X \to Y$  in  $\mathcal{C}$  we define a natural transformation  $h_f: h_X \to h_Y$  given by formula

$$Mor_{\mathcal{C}}(Z, X) \ni g \mapsto f \cdot g \in Mor_{\mathcal{C}}(Z, Y)$$

This defines a functor  $h: \mathcal{C} \to \widehat{\mathcal{C}}$  called the Yoneda embedding of  $\mathcal{C}$ .

**Theorem 3.3** (Yoneda lemma). Let C be a locally small category. For every object  $X \in C$  and a presheaf  $F \in \widehat{C}$  map

$$\operatorname{Mor}_{\widehat{\mathcal{C}}}(h_X, F) \to F(X)$$

given by formula  $p \mapsto p(1_X)$  is a bijection natural in both X and F.

*Proof.* Fix  $p:h_X\to F$  for some  $X\in\mathcal{C}$  and  $F\in\widehat{\mathcal{C}}$ . Denote  $x=p(1_X)$ . Next let  $f:Y\to X$  be a morphism in  $\mathcal{C}$ . Since p is natural transformation, we derive that the diagram

$$h_X(Y) \xrightarrow{p_Y} F(Y)$$

$$h_X(f) \uparrow \qquad \qquad \uparrow F(f)$$

$$h_X(X) \xrightarrow{p_X} F(X)$$

is commutative. Thus  $p_Y(f) = p_Y(h_X(f)(1_X)) = F(f)(x)$ . This shows that for every object  $Y \in \mathcal{C}$  and every morphism  $f: Y \to X$  we have  $p_Y(f) = F(f)(x)$ . Hence p is uniquely determined by x. This proves that the map described in the statement is injective. Now we prove that it is surjective. For this fix an element  $x \in F(X)$  and define  $p:h_X \to F$  by formula  $p_Y(f) = F(f)(x)$  for every morphism  $f: Y \to X$  in  $\mathcal{C}$ . Consider morphisms  $g: Z \to Y$  and  $f: Y \to X$  in  $\mathcal{C}$  and note that

$$F(g)(p_Y(f)) = F(g) \cdot F(f)(x) = F(f \cdot g)(x) = p_Z(f \cdot g) = p_Z(h_X(g)(f))$$

Thus p is a morphism of presheaves and  $p(1_X) = x$ .

It remains to prove that the map in the statement is natural with respect to X and F. This is left to the reader as an exercise.

**Corollary 3.4.** *Let* C *be a locally small category. The functor*  $h: C \to \widehat{C}$  *is full and faithful.* 

*Proof.* Fully faithfulness follows from Theorem 3.3.

Now we investigate small limits and colimits in presheaf categories. For this fix a locally small category  $\mathcal C$  and  $X \in \mathcal C$ . We denote by  $\operatorname{ev}_X : \widehat{\mathcal C} \to \operatorname{\mathbf{Set}}$  the functor that sends a presheaf F to F(X) and a morphism  $f: F \to G$  to  $f_X$ .

**Corollary 3.5.** Fix a locally small category C. Let I be a category and let  $D: I \to \widehat{C}$  be a functor. If I is a small category, then D admits a limit (colimit). Moreover, for a cone (cocone)  $(F, \{f_i\}_{i \in I})$  over D the following assertions are equivalent.

- (i)  $(F, \{f_i\}_{i \in I})$  is a limiting cone (colimiting cocone) over D.
- (ii)  $(F, \{f_i\}_{i \in I})$  is a cone (cocone) over D and for every  $X \in C$  the pair  $(F(X), \{f_{i,X}\}_{i \in I})$  is a limiting cone (colimiting cocone) over  $ev_X \cdot D$ .

*Proof.* By [ML98, V.1, Theorem 1 and Exercise 8] we know that the category **Set** admits both small limits and small colimits. Now it suffices to use Corollary 2.5. □

Finally we add one notational remark. Let C be a locally small category and F, G be presheaves on C. Then we denote by  $\operatorname{Mor}_{C}(F,G)$  the class of morphisms of presheaves with domain F and codomain G.

#### 4. Classes of generators

**Definition 4.1.** Let C be a category. A class K of objects of C is called *a class of generators for* C if for any pair of distinct and parallel arrows

$$X \xrightarrow{f} Y$$

there exists  $Z \in \mathcal{K}$  and a morphism  $h : Z \to X$  such that  $f \cdot h \neq g \cdot h$ .

Now we introduce special case of the notion of the class of generators of category. For this we need one more definition.

**Definition 4.2.** Let  $\mathcal{C}$  be a category and X be an object of  $\mathcal{C}$ . An object of  $\mathcal{C}$  over X is a morphism  $f: Y \to X$  in  $\mathcal{C}$ . If  $f_1: Y_1 \to X$ ,  $f_2: Y_2 \to X$  are objects of  $\mathcal{C}$  over X, then a morphism over X between these objects consists of a morphism  $f: Y_1 \to Y_2$  in  $\mathcal{C}$  such that the following triangle

$$Y_1 \xrightarrow{f} Y_2$$

$$\downarrow^{f_1} X$$

$$X$$

is commutative. This defines the category of objects of C over X.

For every object X of a category  $\mathcal C$  we denote by  $\mathcal C/X$  the category of objects over X. Next suppose that X is an object of  $\mathcal C$  and  $\mathcal K$  is a subclass of the class of objects of  $\mathcal C$ . We denote by  $\mathcal K/X$  the full subcategory of  $\mathcal C/X$  that consists of morphisms  $f:K\to X$  such that K is in  $\mathcal K$ . For every such class we denote by  $\pi_X$  the canonical functor  $\mathcal K/X\to \mathcal K$  that sends every arrow  $f:K\to X$  in  $\mathcal K/X$  to K. In the case of considerations in which multiple distinct classes are involved we specify more precise notation. Next suppose that  $f:X\to Y$  is a morphism in a category  $\mathcal C$ . Then the composition with f induces a functor  $\mathcal C/X\to \mathcal C/Y$ . We denote this functor by  $\mathcal C/f$ . Now if  $\mathcal K$  is a class of objects of  $\mathcal C$ , then we denote by  $\mathcal K/f$  the functor  $\mathcal K/X\to \mathcal K/Y$  induced by  $\mathcal C/f$ .

**Definition 4.3.** Let C be a category and K be a class of objects of C. Suppose that for every object X of C a pair

$$(X, \{f\}_{f \in \mathcal{K}/X})$$

is a colimiting cocone of a functor given as the composition of  $\pi_X : \mathcal{K}/X \to \mathcal{K}$  with the inclusion functor  $\mathcal{K} \hookrightarrow \mathcal{C}$ . Then we call  $\mathcal{K}$  a dense class of generators for  $\mathcal{C}$ .

Let  $\mathcal{C}$  be a locally small category and  $\mathcal{K}$  be a class of objects of  $\mathcal{C}$ . We also denote by  $\mathcal{K}$  the corresponding full subcategory of  $\mathcal{C}$ . We define a functor  $\Gamma_{\mathcal{K}}: \mathcal{C} \to \widehat{\mathcal{K}}$  as the composition of the Yoneda embedding  $\mathcal{C} \to \widehat{\mathcal{C}}$  with the restriction functor  $\widehat{\mathcal{C}} \to \widehat{\mathcal{K}}$ .

**Theorem 4.4.** Let C be a locally small category and K be a class of objects of C. Then the following are equivalent.

- (i) K is a (dense) class of generators for C.
- (ii) The functor

$$\Gamma_{\mathcal{K}}: \mathcal{C} \to \widehat{\mathcal{K}}$$

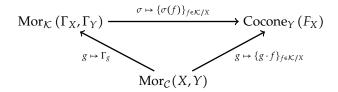

is (full and) faithful.

*Proof.* First we need to introduce some notation. For every object X of  $\mathcal C$  we denote by  $F_X:\mathcal K/X\to\mathcal C$  the functor obtained as the compositon of  $\pi_X:\mathcal K/X\to\mathcal K$  with the inclusion functor  $\mathcal K\to\mathcal C$ . We also denote by  $\Gamma_X$  the value of  $\Gamma$  on X and for every object Y of  $\mathcal C$  we denote by  $\operatorname{Cocone}_Y(F_X)$  the class of cocones with Y as the vertex over the functor  $F_X$ . Finally if  $g:X\to Y$  is a morphism of  $\mathcal C$ , then we denote by  $\Gamma_g$  a natural morphism  $\Gamma_X\to\Gamma_Y$  induced by g.

Suppose now that X and Y are objects of C. Let  $\sigma : \Gamma_X \to \Gamma_Y$  be a natural transformation. Then one can show that  $\{\sigma(f)\}_{f \in \mathcal{K}/X}$  is a cocone of  $F_X$  with vertex in Y and moreover, the map

$$\operatorname{Mor}_{\mathcal{K}}(\Gamma_X, \Gamma_Y) \ni \sigma \mapsto \{\sigma(f)\}_{f \in \mathcal{K}/X} \in \operatorname{Cocone}_{Y}(F_X)$$

is bijective. We have a commutative triangle

From this we derive that  $\Gamma$  is (full and) faithful if and only if

$$\operatorname{Mor}_{\mathcal{C}}(X,Y) \ni g \mapsto \{g \cdot f\}_{f \in \mathcal{K}/X} \in \operatorname{Cocone}_{Y}(F_{X})$$

is (bijective) injective for any pair X, Y of objects in C. This map is (bijective) injective for any pair X, Y of objects in C if and only if K is a class of (dense) generators for C. This proves theorem.  $\Box$ 

**Corollary 4.5.** Let C be a locally small category. Then the class of representable presheaves  $\{h_X\}_{X\in C}$  is a dense class of generators for  $\widehat{C}$ .

*Proof.* We want to apply Theorem 4.4 to  $\widehat{\mathcal{C}}$ . Our issue is that in general  $\widehat{\mathcal{C}}$  is not a locally small category. To fix this we must be specific and work with Grothendieck universes [ML98, page 22]. We assume (c.f. Section 1) that our base Grothendieck universe is U. Then  $\mathbf{Set} = \mathbf{Set}_U$  is the category of U-small sets and  $\mathcal{C}$  is a locally U-small category. Next  $\widehat{\mathcal{C}} = \mathbf{Fun}(\mathcal{C}^{\mathrm{op}}, \mathbf{Set}_U)$  is a presheaf category. Now we fix another universe V that contains U and such that  $\mathcal{C}$  is V-small. We denote by  $\mathbf{Set}_V$  the category of V-small sets. We can apply Theorem 4.4 to a locally V-small category  $\widehat{\mathcal{C}}$ . Consider the composition of the Yoneda embedding  $\widehat{\mathcal{C}} \to \mathbf{Fun}\left((\widehat{\mathcal{C}})^{\mathrm{op}}, \mathbf{Set}_V\right)$  with the restriction  $\mathbf{Fun}\left((\widehat{\mathcal{C}})^{\mathrm{op}}, \mathbf{Set}_V\right) \to \mathbf{Fun}(\mathcal{C}^{\mathrm{op}}, \mathbf{Set}_V)$  induced by the usual Yoneda embedding  $h: \mathcal{C} \to \widehat{\mathcal{C}}$ . The composition is isomorphic with the functor  $\widehat{\mathcal{C}} = \mathbf{Fun}(\mathcal{C}^{\mathrm{op}}, \mathbf{Set}_U) \to \mathbf{Fun}(\mathcal{C}^{\mathrm{op}}, \mathbf{Set}_V)$  induced by the inclusion  $\mathbf{Set}_U \to \mathbf{Set}_V$ . Hence it is full and faithful. Now (replacing our base universe U by V) we can apply Theorem 4.4 to a locally V-small category  $\widehat{\mathcal{C}}$  and derive the statement.

## 5. Internal hom

We start by making few remarks. Let  $\mathcal{C}$  be a locally small category and let X be an object of  $\mathcal{C}$ . Recall that  $\pi_X : \mathcal{C}/X \to \mathcal{C}$  is a functor that sends morphism  $f : Y \to X$  to Y. For every presheaf F on  $\mathcal{C}$  we denote by  $F_{|X}$  the functor

$$F \cdot (\pi_X)^{\mathrm{op}} : (\mathcal{C}/X)^{\mathrm{op}} \to \mathbf{Set}$$

The map  $F \mapsto F_{|X}$  extends to a functor  $\widehat{\mathcal{C}} \to \widehat{\mathcal{C}/X}$ . Let  $\mathbf{1}_{|X}$  denote a presheaf on  $\mathcal{C}/X$  that assigns to every object over X a set with one element. According to Corollary 3.5 we derive that  $\mathbf{1}_{|X}$  is a terminal object in  $\widehat{\mathcal{C}/X}$ .

**Fact 5.1.** Let C be a category and let F be a presheaf on C. Suppose that  $x \in F(X)$  for some X in C. Then x determines a morphism  $\mathbf{1}_{|X} \to F_{|X}$  that for every object f in C/X sends a unique element of  $\mathbf{1}_{|X}(f)$  to  $F(f)(x) \in F_{|X}(f)$ . This gives rise to a bijection

$$F(X) \cong \operatorname{Mor}_{\mathcal{C}/X} \left( \mathbf{1}_{|X}, F_{|X} \right)$$

*Proof.* We left to the reader as an exercise.

Let  $\mathcal{C}$  be a locally small category. If  $f: X \to Y$  is a morphism in  $\mathcal{C}$ , then we have a functor  $\widehat{\mathcal{C}/Y} \to \widehat{\mathcal{C}/X}$  induced by the precomposition with  $(\mathcal{C}/f)^{\mathrm{op}}$ .

**Definition 5.2.** Let C be a locally small category and let F, G be presheaves on C. Assume that for every object X in C the class  $\mathrm{Mor}_{C/X}(F_{|X}, G_{|X})$  is a set. We define

$$\mathcal{M}$$
or <sub>$\mathcal{C}$</sub>   $(F,G)(X) = \mathrm{Mor}_{\mathcal{C}/X}(F_{|X},G_{|X})$ 

for every X in C. This is a presheaf on C, since for every morphism  $f: X \to Y$ , we can compose a morphism  $\sigma: F_{|Y} \to G_{|Y}$  of presheaves with  $(C/f)^{op}$  i.e. we have a map

$$\mathcal{M}$$
or $_{\mathcal{C}}(F,G)(Y) \ni \sigma \mapsto \sigma_{(\mathcal{C}/f)^{\mathrm{op}}} \in \mathcal{M}$ or $_{\mathcal{C}}(F,G)(X)$ 

and these make  $\mathcal{M}$ or $_{\mathcal{C}}(F,G)$  a functor. The presheaf  $\mathcal{M}$ or $_{\mathcal{C}}(F,G)$  is called *an internal hom of F and G*.

Let F, G and H be presheaves on a locally small category C and assume that  $\mathcal{M}$ or $_{C}(F,G)$  exists. Fix a morphism of presheaves  $\sigma: H \times F \to G$ . Pick an object X in C and  $x \in H(X)$ . Let  $i_{x}: \mathbf{1}_{|X} \to H_{|X}$  be a morphism determined by  $x \in H(X)$  as in Fact 5.1. Then  $\sigma_{|X} \cdot \left(i_{x} \times \mathbf{1}_{F_{|X}}\right)$  yields a morphism  $\sigma_{x}: F_{|X} \to G_{|X}$ . Suppose now that  $f: Y \to X$  is a morphism in C. We have

$$\left(\sigma_{|X}\cdot\left(i_{x}\times1_{F_{|X}}\right)\right)_{(\mathcal{C}/f)^{\mathrm{op}}}=\left(\sigma_{|X}\right)_{(\mathcal{C}/f)^{\mathrm{op}}}\cdot\left(\left(i_{x}\right)_{(\mathcal{C}/f)^{\mathrm{op}}}\times\left(1_{F_{|X}}\right)_{(\mathcal{C}/f)^{\mathrm{op}}}\right)=\sigma_{|Y}\cdot\left(i_{F(f)(x)}\times1_{F_{|Y}}\right)$$

because  $(i_x)_{(\mathcal{C}/f)^{\mathrm{op}}} = i_{F(f)(x)}$ . This implies that  $(\sigma_x)_{(\mathcal{C}/f)^{\mathrm{op}}} = \sigma_{F(f)(x)}$ . Hence  $\tau : H \to \mathcal{M}\mathrm{or}_{\mathcal{C}}(F,G)$  given by

$$H(X) \ni x \mapsto \sigma_x \in \operatorname{Mor}_{\mathcal{C}/X} (F_{|X}, G_{|X})$$

is a morphism of presheaves. This defines a map of classes

$$Mor_{\mathcal{C}}(H \times F, G) \in \sigma \mapsto \tau \in Mor_{\mathcal{C}}(H, \mathcal{M}or_{\mathcal{C}}(F, G))$$

**Theorem 5.3.** Let C be a locally small category and F, G be presheaves on C. Assume that for every object X in C the class  $Mor_{C/X}(F_{|X}, G_{|X})$  is a set. Then the map

$$Mor_{\mathcal{C}}(H \times F, G) \rightarrow Mor_{\mathcal{C}}(H, \mathcal{M}or_{\mathcal{C}}(F, G))$$

described above is a bijection natural in H.

*Proof.* The fact that the map in the statement is natural in H is left to the reader as an exercise. Pick an object X in C. We verify now that the map

$$Mor_{\mathcal{C}}(h_X \times F, G) \rightarrow Mor_{\mathcal{C}}(h_X, \mathcal{M}or_{\mathcal{C}}(F, G))$$

is a bijection. Pick a morphism  $\sigma: h_X \times F \to G$  of presheaves and suppose that  $\tau: h_X \to \mathcal{M}\mathrm{or}_{\mathcal{C}}(F,G)$  is its value under the discussed map. According to Yoneda lemma (Theorem 3.3)  $\tau$  is uniquely determined by its value on  $1_X$ . We denote this value by  $\rho$ . Thus it suffices to prove that

$$\operatorname{Mor}_{\mathcal{C}}(h_X \times F, G) \ni \sigma \mapsto \rho \in \operatorname{Mor}_{\mathcal{C}/X}(F_{|X}, G_{|X})$$

is bijective. We retrieve  $\rho$  by means of procedure described before the statement of this theorem. Firstly  $1_X$  according to Fact 5.1 determines a morphism  $i: \mathbf{1}_{|X} \to (h_X)_{|X}$ . Now  $\rho \in \mathrm{Mor}_{\mathcal{C}/X}\left(F_{|X},G_{|X}\right)$  is isomorphic with  $\sigma_{|X}\cdot\left(i\times 1_{F_{|X}}\right)$ . Hence for every  $f:Y\to X$  and  $y\in F(Y)$  we have

$$\rho_f(y) = \sigma_Y(f, y)$$

This implies that  $\sigma$  and  $\rho$  are mutually determined and thus

$$\operatorname{Mor}_{\mathcal{C}}(h_{X} \times F, G) \to \operatorname{Mor}_{\mathcal{C}}(h_{X}, \operatorname{\mathcal{M}or}_{\mathcal{C}}(F, G))$$

is a bijection.

Now we prove the general case. We know that the map

$$\operatorname{Mor}_{\mathcal{C}}(H \times F, G) \to \operatorname{Mor}_{\mathcal{C}}(H, \mathcal{M}\operatorname{or}_{\mathcal{C}}(F, G))$$

is natural in H and is bijective when H is a representable presheaf. Now the following statements hold.

- (1) Every presheaf is canonically the colimit of representable presheaves by Corollary 4.5.
- (2) The functor  $(-) \times F : \widehat{C} \to \widehat{C}$  preserves colimits (this follows from cartesian closedness of **Set** [ML98, page 98] and Corollary 3.5).
- (3) Suppose that V is a Grothendieck universe that contains the base universe U and such that  $\widehat{C}$  is V-locally small. Then the functor

$$\operatorname{Mor}_{\mathcal{C}}(-, \mathcal{M}\operatorname{or}_{\mathcal{C}}(F, G)) : \widehat{\mathcal{C}} \to \operatorname{\mathbf{Set}}_{V}$$

preserves colimits [ML98, V.4, Theorem 1].

Therefore, we derive that the map in the question is bijective for every presheaf H.

#### 6. Subpresheaves of internal hom

Let  $\mathcal{C}$  be a locally small category and let F, G be a presheaves on  $\mathcal{C}$ . The requirement that  $\mathrm{Mor}_{\mathcal{C}/X}\left(F_{|X},G_{|X}\right)$  is a set for every object X in  $\mathcal{C}$  is a serious limitation of Theorem 5.3. In this section we explain a useful result which addresses this issue.

**Definition 6.1.** Let  $\mathcal{C}$  be a locally small category and let F, G, J be presheaves on  $\mathcal{C}$ . Suppose that for every object X in  $\mathcal{C}$  there exists an inclusion of classes  $J(X) \subseteq \operatorname{Mor}_{\mathcal{C}/X}(F_{|X}, G_{|X})$  such that the square of maps (horizontal arrows in the square are inclusions) of classes

$$J(Y) \longleftrightarrow \operatorname{Mor}_{\mathcal{C}/Y} \left( F_{|Y}, G_{|Y} \right)$$

$$J(f) \downarrow \qquad \qquad \downarrow^{\sigma \mapsto \sigma_{(\mathcal{C}/f)^{\operatorname{op}}}}$$

$$J(X) \longleftrightarrow \operatorname{Mor}_{\mathcal{C}/X} \left( F_{|X}, G_{|X} \right)$$

is commutative for every morphism  $f: X \to Y$  in C. Then we say that J is a subpresheaf of internal hom of F and G.

Let  $\mathcal{C}$  be a locally small category, F, G, H be presheaves on  $\mathcal{C}$ . Fix a morphism  $\sigma: H \times F \to G$  of presheaves. Recall form the previous section that for every object X in  $\mathcal{C}$  and x in H(X) we denote by  $i_x: \mathbf{1}_{|X} \to H_{|X}$  a unique morphism determined by x (Fact 5.1). Next we denote by  $\sigma_x: F_{|X} \to G_{|X}$  a unique morphism isomorphic with  $\sigma_{|X} \cdot (i_x \times 1_{F_{|X}})$ .

**Definition 6.2.** Let  $\mathcal{C}$  be a locally small category, F, G, H be presheaves on  $\mathcal{C}$  and assume that J is a subpresheaf of internal hom of F and G. Then a morphism of presheaves  $\sigma: H \times F \to G$  is called a family of J-morphisms parametrized by H if for every object X in  $\mathcal{C}$  and every x in H(X) we have  $\sigma_X \in J(X)$ .

We continue discussion started before the definition. Let us now assume that  $\sigma: H \times F \to G$  is a family of *J*-morphisms parametrized by *H* for some subpresheaf *J* of internal hom of *F* and *G*. Then  $\tau: H \to J$  given by

$$H(X) \ni x \mapsto \sigma_x \in J(X)$$

is a morphism of presheaves. The proof is identical to the proof of the analogous statement preceding Theorem 5.3. This gives rise to a map of classes

{families of *J*-morphisms parametrized by 
$$H$$
}  $\ni \sigma \mapsto \tau \in Mor_{\mathcal{C}}(H, J)$ 

**Theorem 6.3.** Let C be a locally small category and F, G be presheaves on C. Assume that J is a subpresheaf of internal hom of F and G. Then the map

$$\{families \ of \ J\text{-morphisms parametrized by } H\} \rightarrow \operatorname{Mor}_{\mathcal{C}}(H,J)$$

described above is a bijection natural in H.

*Proof.* We enlarge our base universe U to a Grothendieck universe V such that  $\mathcal{C}$  is V-small. Then  $\mathcal{M}$ or $_{\mathcal{C}}(F,G) \in \mathbf{Fun}(\mathcal{C}^{\mathrm{op}},\mathbf{Set}_{V})$  and J is a legitimate subobject of  $\mathcal{M}$ or $_{\mathcal{C}}(F,G)$  in  $\mathbf{Fun}(\mathcal{C}^{\mathrm{op}},\mathbf{Set}_{V})$ . For every  $H \in \widehat{\mathcal{C}} = \mathbf{Fun}(\mathcal{C}^{\mathrm{op}},\mathbf{Set}_{U}) \subseteq \mathbf{Fun}(\mathcal{C}^{\mathrm{op}},\mathbf{Set}_{V})$  we have a bijection

$$Mor_{\mathcal{C}}(H \times F, G) \rightarrow Mor_{\mathcal{C}}(H, \mathcal{M}or_{\mathcal{C}}(F, G))$$

natural in H. This follows according to Theorem 5.3 applied to the enlarged category of presheaves  $Fun(\mathcal{C}^{op}, Set_V)$ . Finally this bijection induces a bijection

{families of *J*-morphisms parametrized by 
$$H$$
}  $\rightarrow$  Mor $_{\mathcal{C}}(H, J)$ 

on its subclasses, which is natural in H and is given by the rule described in the discussion preceding the statement of the theorem.

## 7. REMARKS ON CATEGORIES OF COPRESHEAVES

**Definition 7.1.** Let C be a locally small category. The category Fun(C, Set) is called *the category of copresheaves on C.* 

All results stated above for categories of presheaves hold for categories of copresheaves by virtue of the identification

$$\mathbf{Fun}\left(\mathcal{C},\mathbf{Set}\right)=\mathbf{Fun}\left(\left(\mathcal{C}^{\mathrm{op}}\right)^{\mathrm{op}},\mathbf{Set}\right)$$
